NEW QUESTION # 137

What is a function of a proxy server?

- A. It responds to user queries to create, manipulate, and retrieve records from a database.
- **B. It acts as a giant cache of web pages that anyone in the organization has recently retrieved.**
- C. It stores files that any user of the network may wish to access.
- D. It responds to HTTP requests and can execute scripts to generate dynamic pages.

Answer: B

Explanation:

A proxy server serves several essential functions in network communication:

1. Security and Privacy:

o A proxy server acts as a gateway between the user's device and the internet. When a user sends a request (e.g., accessing a website), it first goes through the proxy server.

o The proxy server hides the user's IP address, making it difficult for external entities to directly trace the user's location or identity.

o By acting as an intermediary, the proxy server provides an additional layer of security, protecting the internal network from potential threats and attacks.

2. Content Filtering and Access Control:

o Organizations often use proxy servers to control internet access for their employees. The proxy can filter requests based on predefined rules.

o For example, an organization might block access to certain websites (e.g., social media, gambling sites) or restrict access during work hours.

o Content filtering helps maintain productivity and prevent unauthorized access to inappropriate or harmful content.

3. Caching and Acceleration:

o Proxy servers can cache frequently accessed web pages, images, and files. When a user requests the same content again, the proxy serves it from its cache.

o Caching reduces the load on the internet connection and speeds up access to commonly visited sites.

o It also helps save bandwidth by minimizing redundant data transfers.

4. Load Balancing:

o In large networks, multiple proxy servers can distribute incoming requests to different web servers. This load balancing ensures efficient utilization of resources.

o By evenly distributing traffic, proxy servers prevent any single server from becoming overwhelmed.

5. Anonymity and Geolocation Bypass:

oSome users use proxy servers to hide their real IP addresses. This anonymity can be useful for privacy reasons or to bypass geolocation restrictions.

oFor example, a user in one country can use a proxy server located in another country to access region-restricted content.

NEW QUESTION # 138

What is true about an operating system?

- A. It is an application program similar to word processors.
- B. It is a firmware burned onto the computer mother board.
- C. It is a hardware component of the computer system.
- **D. It is a software program that directly supports the computer itself.**

Answer: D

Explanation:

An operating system (OS) is a crucial component of the computer system. It is not firmware, which would be embedded into the hardware (eliminating option A), nor is it an application program like a word processor (eliminating option B). It is also not a hardware component (eliminating option D). Instead, an operating system is system software that manages computer hardware and software resources and provides common services for computer programs. This includes managing processes, memory, files, security, and input/output operations. The OS acts as an intermediary between applications and the computer hardware, making it possible for other software to run on the computer.

NEW QUESTION # 139

Which hardware component stores instructions for critical system activities?

- A. Central processing unit CPU
- B. Graphics processing unit GPU
- C. Random-access memory RAM
- **D. Read-only memory ROM**

Answer: D

Explanation:

Read-only memory, or ROM, stores instructions for critical system activities, especially the firmware used during startup. In Information Technology fundamentals, ROM contains non-volatile instructions that remain available even when the computer is powered off. These instructions typically include the system firmware responsible for initializing hardware, performing basic checks, and starting the boot process that loads the operating system. Because ROM is designed to retain its contents without power, it is appropriate for storing essential routines that the computer must access immediately when it turns on. RAM is volatile and loses contents when power is removed, so it cannot reliably store permanent startup instructions. The CPU executes instructions but does not store firmware permanently. The GPU is a specialized processor for graphics and parallel workloads and is not responsible for storing core boot instructions. Although modern systems often use flash-based firmware rather than older fixed ROM chips, this is still categorized as ROM or ROM-like non-volatile firmware storage in many IT documents. Therefore, the correct component is ROM.

NEW QUESTION # 140

What can applications use to interact with a database?

- A. Operating System
- **B. SQL**
- C. IIAS
- D. Java Database Connectivity

Answer: B

Explanation:

SQL is the standard language for communicating with relational databases. Applications use SQL to:

*Retrieve data: SELECT queries are used to fetch specific data from database tables.

*Modify data: INSERT, UPDATE, and DELETE statements allow applications to add, change, or remove data in the database.

*Manage database structure: CREATE, ALTER, and DROP statements let applications create tables, modify their structure, or delete them entirely.
