CompTIA DataSys+ Certification Exam Sample Questions (Q150-Q155):

NEW QUESTION # 150

Which of the following computer services associates IP network addresses with text-based names in order to facilitate identification and connectivity?

- A. DNS
- B. DHCP
- C. LDAP
- D. NTP

Answer: A

Explanation:

The computer service that associates IP network addresses with text-based names in order to facilitate identification and connectivity is IDNS. IDNS, or Internet Domain Name System (DNS), is a service that translates domain names into IP addresses and vice versa. Domain names are human- readable names that identify websites or devices on the internet, such as www.comptia.org or www.google.com. IP addresses are numerical identifiers that locate websites or devices on the internet, such as 104.18.26.46 or 142.250.72.238. IDNS helps users to access websites or devices using domain names instead of IP addresses, which are easier to remember and type. IDNS also helps administrators to manage websites or devices using domain names instead of IP addresses, which are more flexible and scalable. The other options are either different computer services or not related to IP network addresses or text-based names at all. For example, LDAP, or Lightweight Directory Access Protocol, is a service that provides access to directory information such as users, groups, or devices on a network; NTP, or Network Time Protocol, is a service that synchronizes the clocks of computers or devices on a network; DHCP, or Dynamic Host Configuration Protocol, is a service that assigns IP addresses and other network configuration parameters to computers or devices on a network.

NEW QUESTION # 151

Which of the following indexes stores records in a tabular format?

- A. Non-clustered
- B. Secondary
- C. Unique

- **D. Columnstore**

Answer: D

Explanation:

The index that stores records in a tabular format is columnstore. A columnstore index is a type of index that stores and compresses data by columns rather than by rows. A columnstore index can improve the performance and efficiency of queries that perform aggregations, calculations, or analysis on large amounts of data, such as data warehouse or business intelligence applications. A columnstore index can also reduce the storage space required for data by applying various compression techniques, such as dictionary encoding, run-length encoding, bit packing, etc. The other options are either different types of indexes or not related to indexes at all. For example, a non-clustered index is a type of index that stores the values of one or more columns in a sorted order along with pointers to the corresponding rows in the table; a unique index is a type of index that enforces uniqueness on one or more columns in a table; a secondary index is an alternative term for a non-clustered index.

NEW QUESTION # 152

Which of the following is a result of an on-path attack on a system?

- **A. A Wi-Fi network that redirects to clones of legitimate websites**
- B. A web application that returns the addresses of its customers
- C. An email from an unknown source requesting bank account details
- D. A website that has crashed and is no longer accessible

Answer: A

Explanation:

A result of an on-path attack on a system is a Wi-Fi network that redirects to clones of legitimate websites. An on-path attack is a type of attack that intercepts and modifies the traffic between two parties without their knowledge or consent. An attacker can use an on-path attack to create a rogue Wi-Fi network that mimics a legitimate one, and then redirect the users to fake websites that look like the ones they intended to visit. The attacker can then steal the users' personal or financial information, such as usernames, passwords, credit card numbers, or bank account details. The other options are either results of different types of attacks or not related to attacks at all. For example, a website that has crashed and is no longer accessible may be a result of a denial-of-service attack, an email from an unknown source requesting bank account details may be a result of a phishing attack, and a web application that returns the addresses of its customers may be a result of a poor design or a data breach.

NEW QUESTION # 153

A database administrator needs to aggregate data from multiple tables in a way that does not impact the original tables, and then provide this information to a department. Which of the following is the best way for the administrator to accomplish this task?

- A. Create indexes on those tables.
- B. Create a function.
- C. Create a new database.
- **D. Create a materialized view.**

Answer: D

Explanation:

The best way for the administrator to accomplish this task is to create a materialized view. A materialized view is a type of view that stores the result of a query on one or more tables as a separate table in the database. A materialized view can aggregate data from multiple tables in a way that does not impact the original tables, and then provide this information to a department as a single source of truth. A materialized view also improves query performance and efficiency by reducing the need to recompute complex queries every time they are executed. The other options are either not suitable or not optimal for this task. For example, creating indexes on those tables may improve query performance on individual tables, but not on aggregated data; creating a new database may require additional resources and maintenance, and may introduce inconsistency or redundancy; creating a function may require additional coding and execution, and may not store the result as a separate table.

NEW QUESTION # 154

Which of the following code snippets would allow a SQL injection?

```
var name;
```

- A. `var SQL = "Select * from sample_database where name = ' " + name + "'";`
- B. `name= request.form("name");`
`var SQL = "Select * from sample_database where name = ' " + name + "'";`
`var name;`
- C. `var name = "Select * from sample_database where name = ' " + name + "'";`
`var name;`
- D. `name= request.form("name");`
`var name;`

Answer: B

Explanation:

This code directly concatenates user input into an SQL query string without validation or parameterization, making it vulnerable to SQL injection attacks.
