We provide 3 versions of our PCEP - Certified Entry-Level Python Programmer exam torrent and they include PDF version, PC version, APP online version. Each version's functions and using method are different and you can choose the most convenient version which is suitable for your practical situation. For example, the PDF version is convenient for you to download and print our PCEP-30-02 test torrent and is suitable for browsing learning. If you use the PDF version you can print our PCEP-30-02 Guide Torrent on the papers and it is convenient for you to take notes. You learn our PCEP-30-02 test torrent at any time and place. The PC version can stimulate the real exam's environment, is stalled on the Windows operating system and runs on the Java environment. You can use it at any time to test your own exam stimulation tests scores and whether you have mastered our PCEP-30-02 guide torrent or not.

Our experts have been dedicated in this area for more than ten years. They all have a good command of exam skills to cope with the PCEP-30-02 preparation materials efficiently in case you have limited time to prepare for it, because all questions within them are professionally co-related with the PCEP-30-02 exam. Our PCEP-30-02 practice braindumps will be worthy of purchase, and you will get manifest improvement. So you have a comfortable experience with our PCEP-30-02 study guide this time.

Accurate PCEP-30-02 Study Material | Latest PCEP-30-02 Test Materials

As the captioned description said, our PCEP-30-02 practice materials are filled with the newest points of knowledge about the exam. With many years of experience in this line, we not only compile real test content into our PCEP-30-02 practice materials, but the newest in to them. Allowing for there is a steady and growing demand for our PCEP-30-02 practice materials with high quality at moderate prices, we never stop the pace of doing better. All newly supplementary updates will be sent to your mailbox one year long. And we shall appreciate it if you choose any version of our PCEP-30-02 practice materials for exam and related tests in the future.

Python Institute PCEP-30-02 Exam Syllabus Topics:

Topic	Details
Topic 1	parameters, arguments, and scopes. It also covers Recursion, Exception hierarchy, Exception handling, etc.
Topic 2	Data Collections: In this section, the focus is on list construction, indexing, slicing, methods, and comprehensions; it covers Tuples, Dictionaries, and Strings.
Topic 3	Loops: while, for, range(), loops control, and nesting of loops.
Topic 4	Functions and Exceptions: This part of the exam covers the definition of function and invocation

Python Institute PCEP - Certified Entry-Level Python Programmer Sample Questions (Q10-Q15):

NEW QUESTION # 10

Assuming that the phone_dir dictionary contains name:number pairs, arrange the code boxes to create a valid line of code which adds Oliver Twist's phone number (5551122333) to the directory.

Answer:

Explanation:

```
phone_dir["Oliver Twist"] = ["5551122333"]
```

Explanation:

To correctly add Oliver Twist's phone number to the phone_dir dictionary, the code must follow this phone_dir["Oliver Twist"] = ["5551122333"] Now, let's match that with your code boxes and arrange them:

```
* phone_dir
* [
* "Oliver Twist"
* ]
* =
* [
* "5551122333"
* ]
```

Final Order: phone_dir # [# "Oliver Twist" #] # = # [# "5551122333" #]

NEW QUESTION # 11

What is true about exceptions and debugging? (Select two answers.)

- A. If some Python code is executed without errors, this proves that there are no errors in it.
- **B. A tool that allows you to precisely trace program execution is called a debugger.**
- C. The default (anonymous) except branch cannot be the last branch in the try-except block.
- **D. One try-except block may contain more than one except branch.**

Answer: B,D

Explanation:

Exceptions and debugging are two important concepts in Python programming that are related to handling and preventing errors. Exceptions are errors that occur when the code cannot be executed properly, such as syntax errors, type errors, index errors, etc. Debugging is the process of finding and fixing errors in the code, using various tools and techniques. Some of the facts about exceptions and debugging are:

* A tool that allows you to precisely trace program execution is called a debugger. A debugger is a program that can run another program step by step, inspect the values of variables, set breakpoints, evaluate expressions, etc. A debugger can help you find the source and cause of an error, and test possible solutions. Python has a built-in debugger module called `pdb`, which can be used from the command line or within the code. There are also other third-party debuggers available for Python, such as PyCharm, Visual Studio Code, etc¹²

* If some Python code is executed without errors, this does not prove that there are no errors in it. It only means that the code did not encounter any exceptions that would stop the execution. However, the code may still have logical errors, which are errors that cause the code to produce incorrect or unexpected results. For example, if you write a function that is supposed to calculate the area of a circle, but you use the wrong formula, the code may run without errors, but it will give you the wrong answer. Logical errors are harder to detect and debug than syntax or runtime errors, because they do not generate any error messages. You have to test the code with different inputs and outputs, and compare them with the expected results³⁴

* One try-except block may contain more than one except branch. A try-except block is a way of handling exceptions in Python, by using the keywords `try` and `except`. The `try` block contains the code that may raise an exception, and the `except` block contains the code that will execute if an exception occurs. You can have multiple `except` blocks for different types of exceptions, or for different actions to take. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except ZeroDivisionError: # handle the ZeroDivisionError exception
except: # handle any other exception
```

This way, you can customize the error handling for different situations, and provide more informative messages or alternative solutions⁵

* The default (anonymous) `except` branch can be the last branch in the try-except block. The default `except` branch is the one that does not specify any exception type, and it will catch any exception that is not handled by the previous `except` branches. The default `except` branch can be the last branch in the try- except block, but it cannot be the first or the only branch. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except: # handle any other exception
```

This is a valid try-except block, and the default `except` branch will be the last branch. However, you cannot write a try-except block like this:

```
try: # some code that may raise an exception
except: # handle any exception
```

This is an invalid try-except block, because the default `except` branch is the only branch, and it will catch all exceptions, even those that are not errors, such as `KeyboardInterrupt` or `SystemExit`. This is considered a bad practice, because it may hide or ignore important exceptions that should be handled differently or propagated further. Therefore, you should always specify the exception types that you want to handle, and use the default `except` branch only as a last resort⁵ Therefore, the correct answers are A. A tool that allows you to precisely trace program execution is called a debugger. and C. One try-except block may contain more than one except branch.

NEW QUESTION # 12

A set of rules which defines the ways in which words can be coupled in sentences is called:

- A. dictionary
- B. lexis
- C. semantics
- **D. syntax**

Answer: D

Explanation:

Syntax is the branch of linguistics that studies the structure and rules of sentences in natural languages. Lexis is the vocabulary of a language. Semantics is the study of meaning in language. A dictionary is a collection of words and their definitions, synonyms, pronunciations, etc.

NEW QUESTION # 13

Assuming that the following assignment has been successfully executed:

```
the_list = ["1", 1, 1, 1]
```

Which of the following expressions evaluate to True? (Select two expressions.)

- A. `the_list.index {"1"} in the_list`
- B. `len(the_list[0:2]) < 3`
- C. `1.1 in the_list[1:3]`
- D. `the_list.index {"1"} == 0`

Answer: B,D

Explanation:

The code snippet that you have sent is assigning a list of four values to a variable called "the_list". The code is as follows:

```
the_list = ['1', 1, 1, 1]
```

The code creates a list object that contains the values '1', 1, 1, and 1, and assigns it to the variable "the_list".

The list can be accessed by using the variable name or by using the index of the values. The index starts from 0 for the first value and goes up to the length of the list minus one for the last value. The index can also be negative, in which case it counts from the end of the list. For example, `the_list[0]` returns '1', and `the_list[-1]` returns 1.

The expressions that you have given are trying to evaluate some conditions on the list and return a boolean value, either True or False. Some of them are valid, and some of them are invalid and will raise an exception.

An exception is an error that occurs when the code cannot be executed properly. The expressions are as follows:

A). `the_list.index {"1"} in the_list`: This expression is trying to check if the index of the value '1' in the list is also a value in the list. However, this expression is invalid, because it uses curly brackets instead of parentheses to call the index method. The index method is used to return the first occurrence of a value in a list. For example, `the_list.index('1')` returns 0, because '1' is the first value in the list. However, `the_list.index`

`{"1"}` will raise a `SyntaxError` exception and output nothing.

B). `1.1 in the_list[1:3]`: This expression is trying to check if the value 1.1 is present in a sublist of the list.

However, this expression is invalid, because it uses a vertical bar instead of a colon to specify the start and end index of the sublist. The sublist is obtained by using the slicing operation, which uses square brackets and a colon to get a part of the list. For example, `the_list[1:3]` returns [1, 1], which is the sublist of the list from the index 1 to the index 3, excluding the end index. However, `the_list[1:3]` will raise a `SyntaxError` exception and output nothing.

C). `len(the_list[0:2]) < 3`: This expression is trying to check if the length of a sublist of the list is less than 3.

This expression is valid, because it uses the `len` function and the slicing operation correctly. The `len` function is used to return the number of values in a list or a sublist. For example, `len(the_list)` returns 4, because the list has four values. The slicing operation is used to get a part of the list by using square brackets and a colon. For example, `the_list[0:2]` returns ['1', 1], which is the sublist of the list from the index 0 to the index 2, excluding the end index. The expression `len(the_list[0:2]) < 3` returns True, because the length of the sublist ['1', 1] is 2, which is less than 3.

D). `the_list.index {"1"} == 0`: This expression is trying to check if the index of the value '1' in the list is equal to 0. This expression is valid, because it uses the index method and the equality operator correctly. The index method is used to return the first occurrence of a value in a list. For example, `the_list.index('1')` returns 0, because '1' is the first value in the list. The equality operator is used to compare two values and return True if they are equal, or False if they are not. For example, `0 == 0` returns True, and `0 == 1` returns False. The expression `the_list.index {"1"} == 0` returns True, because the index of '1' in the list is 0, and 0 is equal to 0.

Therefore, the correct answers are C. `len(the_list[0:2]) < 3` and D. `the_list.index {"1"} == 0`.

Answer: B,D

Therefore, the correct answers are C. `len(the_list[0:2]) < 3` and D. `the_list.index {'1'} == 0`.
