## WGU Managing Cloud Security (JY02) Sample Questions (Q29-Q34):

### NEW QUESTION # 29

An organization is considering using vendor-specific application programming interfaces (APIs) and internal tools to set up a new service. However, the engineers are against this plan and are advocating for a new policy to prevent issues that could arise. Which common concern in cloud applications are the engineers concerned about?

- A. Reliability
- B. Availability
- C. Portability
- D. Scalability

**Answer: C**

Explanation:

The engineers are concerned about portability. Vendor-specific APIs and tools create a dependency on a single provider, leading to vendor lock-in. This limits the ability to migrate services or workloads to another provider without significant rework.

Reliability and availability refer to service uptime and continuity, while scalability addresses performance under demand. Although important, none of these directly relate to cross-platform flexibility. Portability ensures that services, data, and applications can be easily moved or integrated across environments.

By adopting portable solutions—such as open standards, containerization, and multi-cloud strategies—organizations reduce long-term risks, increase negotiation power with providers, and enhance resilience.

### NEW QUESTION # 30

Which steps should an organization take to avoid risk when dealing with software licensing?

- A. It should ensure it has the correct type of license.
- B. It should ensure it only uses open-source licenses.
- C. It should ensure it has the correct location to store licenses.
- D. It should ensure it only uses closed-source licenses.

**Answer: A**

Explanation:

The primary safeguard against licensing risk is ensuring the organization has the correct type of license.

Software licenses define usage rights, limitations, and legal obligations. Using software outside of license terms can lead to legal penalties, financial fines, and reputational damage.

Location of licenses is a management issue, not a risk control. Restricting usage to closed-source or open-source alone is not practical, as both models require compliance with license agreements.

Correct licensing includes verifying user counts, subscription terms, geographic restrictions, and intended use.

It also involves monitoring for unauthorized installations and conducting regular audits. Proper license management ensures legal compliance, cost control, and operational continuity.

### NEW QUESTION # 31

An organization is implementing a new hybrid cloud deployment. Before granting access to any of the resources, the security team wants to ensure that all employees are checked against a database to see if they are allowed to access the requested resource.

Which type of security control is the organization leveraging for its employees?

- A. Web application firewall (WAF)
- B. Authentication
- C. Antispyware program
- D. Authorization

**Answer: D**

Explanation:

The described control is authorization, which occurs after authentication. Authorization determines what resources a user can access based on their role, attributes, or policies stored in an access control database.

Authentication confirms identity, but authorization validates permissions. WAFs protect applications from malicious traffic, and antispayware tools detect malware. Neither applies to access decisions.

By checking users against a database of permissions, the organization enforces the principle of least privilege, ensuring employees only access the resources necessary for their role. This strengthens data protection, reduces insider threats, and aligns with compliance requirements for access governance.

### NEW QUESTION # 32

Which concept focuses on operating highly available workloads in the cloud?

- A. Resource hierarchy
- B. Security
- **C. Reliability**
- D. Operational excellence

**Answer: C**

Explanation:

Reliability in cloud design ensures workloads can recover quickly from disruptions and continue operating as expected. This concept focuses on high availability, fault tolerance, and disaster recovery. Reliability requires implementing redundancy, backup strategies, and robust monitoring.

Security ensures data protection, operational excellence covers continuous improvement, and resource hierarchy refers to organizational structures, but none focus specifically on availability and resilience.

By prioritizing reliability, organizations design cloud architectures capable of withstanding failures at multiple layers—compute, storage, networking, and even regions. This design principle ensures customer trust and compliance with service-level agreements.

### NEW QUESTION # 33

An organization wants to ensure that all entities trust any certificate generated internally in the organization.

What should be used to generate these certificates?

- A. Individual systems' private keys
- **B. The organization's certificate authority server**
- C. Individual users' private keys
- D. The organization's certificate repository server

**Answer: B**

Explanation:

Trust in digital certificates comes from their issuance by a Certificate Authority (CA). A CA is a trusted entity that validates identities and signs certificates. In internal environments, organizations often operate a private CA to issue certificates for users, systems, and services.

If certificates were generated by individual private keys or systems without central authority, there would be no unified trust chain, and validating authenticity across the organization would be impossible. A certificate repository server only distributes certificates but cannot establish trust.

By using an organizational CA server, all certificates are linked to a root of trust. Systems configured to trust the organization's CA will trust any certificate it issues. This allows secure internal communications (TLS, VPN, email signing) and ensures scalability as new services come online. It also supports compliance with enterprise PKI policies.
