

# PCEP-30-02 Actual Exams, PCEP-30-02 Valid Test Simulator

P.S. Free 2026 Python Institute PCEP-30-02 dumps are available on Google Drive shared by DumpsQuestion: [https://drive.google.com/open?id=1vt0fHUS41NS3IfhXFt9\\_GoUcyL4BuW-](https://drive.google.com/open?id=1vt0fHUS41NS3IfhXFt9_GoUcyL4BuW-)

Knowledge of the PCEP-30-02 real study dumps contains are very comprehensive, not only have the function of online learning, also can help the user to leak fill a vacancy, let those who deal with qualification exam users can easily and efficient use of the PCEP-30-02 question guide. By visit our website, the user can obtain an experimental demonstration, free after the user experience can choose the most appropriate and most favorite PCEP-30-02 Exam Questions download. Users can not only learn new knowledge, can also apply theory into the actual problem, but also can leak fill a vacancy, can say such case selection is to meet, so to grasp the opportunity!

We strongly recommend using our PCEP-30-02 exam dumps to prepare for the PCEP - Certified Entry-Level Python Programmer. It is the best way to ensure success. With our PCEP-30-02 practice questions, you can get the most out of your studying and maximize your chances of passing your PCEP-30-02 Exam. DumpsQuestion PCEP - Certified Entry-Level Python Programmer is the answer if you want to score higher in the PCEP-30-02 exam and achieve your academic goals.

## PCEP-30-02 Valid Test Simulator, Prep PCEP-30-02 Guide

DumpsQuestion provides proprietary preparation guides for the certification exam offered by the PCEP-30-02 exam dumps. In addition to containing numerous questions similar to the PCEP-30-02 exam, the PCEP-30-02 Exam Questions are a great way to

prepare for the PCEP-30-02 exam dumps. The Python Institute PCEP-30-02 mock exam setup can be configured to a particular style and arrive at unique questions.

## Python Institute PCEP-30-02 Exam Syllabus Topics:

Topic	Details
Topic 1	<ul style="list-style-type: none"><li>• Functions and Exceptions: This part of the exam covers the definition of function and invocation</li></ul>
Topic 2	<ul style="list-style-type: none"><li>• Computer Programming Fundamentals: This section of the exam covers fundamental concepts such as interpreters, compilers, syntax, and semantics. It covers Python basics: keywords, instructions, indentation, comments in addition to Booleans, integers, floats, strings, and Variables, and naming conventions. Finally, it covers arithmetic, string, assignment, bitwise, Boolean, relational, and Input</li><li>• output operations.</li></ul>
Topic 3	<ul style="list-style-type: none"><li>• Data Collections: In this section, the focus is on list construction, indexing, slicing, methods, and comprehensions; it covers Tuples, Dictionaries, and Strings.</li></ul>

## Python Institute PCEP - Certified Entry-Level Python Programmer Sample Questions (Q42-Q47):

### NEW QUESTION # 42

Assuming that the following assignment has been successfully executed:

```
My_list = [1, 1, 2, 3]
```

Select the expressions which will not raise any exception.

(Select two expressions.)

- A. `my_list[0:1]`
- B. `my_list[-10]`
- C. `my_list|my_list | 3| 1`
- D. `my_list [6]`

**Answer: A,C**

Explanation:

Explanation

The code snippet that you have sent is assigning a list of four numbers to a variable called "my\_list". The code is as follows:

```
my_list = [1, 1, 2, 3]
```

The code creates a list object that contains the elements 1, 1, 2, and 3, and assigns it to the variable "my\_list".

The list can be accessed by using the variable name or by using the index of the elements. The index starts from 0 for the first element and goes up to the length of the list minus one for the last element. The index can also be negative, in which case it counts from the end of the list. For example, `my_list[0]` returns 1, and `my_list[-1]` returns 3.

The code also allows some operations on the list, such as slicing, concatenation, repetition, and membership.

Slicing is used to get a sublist of the original list by specifying the start and end index. For example, `my_list[1:3]` returns [1, 2].

Concatenation is used to join two lists together by using the + operator. For example, `my_list + [4, 5]` returns [1, 1, 2, 3, 4, 5].

Repetition is used to create a new list by repeating the original list a number of times by using the \* operator. For example, `my_list * 2` returns [1, 1, 2, 3, 1, 1, 2, 3].

Membership is used to check if an element is present in the list by using the in operator. For example, `2 in my_list` returns True, and `4 in my_list` returns False.

The expressions that you have given are trying to access or manipulate the list in different ways. Some of them are valid, and some of them are invalid and will raise an exception. An exception is an error that occurs when the code cannot be executed properly. The expressions are as follows:

A). `my_list[-10]`: This expression is trying to access the element at the index -10 of the list. However, the list only has four elements, so the index -10 is out of range. This will raise an `IndexError` exception and output nothing.

B). `my_list|my_list | 3| 1`: This expression is trying to perform a bitwise OR operation on the list and some other operands. The bitwise OR operation is used to compare the binary representation of two numbers and return a new number that has a 1 in each bit position where either number has a 1. For example, `3 | 1` returns 3, because 3 in binary is 11 and 1 in binary is 01, and 11 | 01 is 11. However, the bitwise OR operation cannot be applied to a list, because a list is not a number. This will raise a `TypeError` exception and output nothing.

C). `my_list[6]`: This expression is trying to access the element at the index 6 of the list. However, the list only has four elements, so the index 6 is out of range. This will raise an `IndexError` exception and output nothing.

D). `my_List- [0:1]`: This expression is trying to perform a subtraction operation on the list and a sublist. The subtraction operation is used to subtract one number from another and return the difference. For example, `3 - 1` returns 2. However, the subtraction operation cannot be applied to a list, because a list is not a number. This will raise a `TypeError` exception and output nothing. Only two expressions will not raise any exception. They are:

B). `my_list|my_List | 3| I`: This expression is not a valid Python code, but it is not an expression that tries to access or manipulate the list. It is just a string of characters that has no meaning. Therefore, it will not raise any exception, but it will also not output anything.

D). `my_List- [0:1]`: This expression is a valid Python code that uses the slicing operation to get a sublist of the list. The slicing operation does not raise any exception, even if the start or end index is out of range. It will just return an empty list or the closest possible sublist. For example, `my_list[0:10]` returns `[1, 1, 2, 3]`, and `my_list[10:20]` returns `[]`. The expression `my_List- [0:1]` returns the sublist of the list from the index 0 to the index 1, excluding the end index. Therefore, it returns `[1]`. This expression will not raise any exception, and it will output `[1]`.

Therefore, the correct answers are B. `my_list|my_List | 3| I` and D. `my_List- [0:1]`.

### NEW QUESTION # 43

What is the expected output of the following code?

- A. 0
- B. ppt
- C. The code is erroneous and cannot be run.
- D. pizzapastafolpetti

**Answer: B**

Explanation:

The code snippet that you have sent is using the slicing operation to get parts of a string and concatenate them together. The code is as follows:

```
pizza = "pizza" pasta = "pasta" folpetti = "folpetti" print(pizza[0] + pasta[0] + folpetti[0])
```

The code starts with assigning the strings "pizza", "pasta", and "folpetti" to the variables `pizza`, `pasta`, and `folpetti` respectively. Then, it uses the `print` function to display the result of concatenating the first characters of each string. The first character of a string can be accessed by using the index 0 inside square brackets. For example, `pizza[0]` returns "p". The concatenation operation is used to join two or more strings together by using the `+` operator. For example, `"a" + "b"` returns "ab". The code prints the result of `pizza[0] + pasta[0] + folpetti[0]`, which is "p" + "p" + "t", which is "ppt".

The expected output of the code is ppt, because the code prints the first characters of each string. Therefore, the correct answer is B. ppt.

### NEW QUESTION # 44

What is the expected result of the following code?

- A. The code is erroneous and cannot be run.
- B. 0
- C. 1
- D. 2

**Answer: A**

Explanation:

Explanation

The code snippet that you have sent is trying to use the global keyword to access and modify a global variable inside a function. The code is as follows:

```
speed = 10 def velocity(): global speed speed = speed + 10 return speed print(velocity())
```

The code starts with creating a global variable called "speed" and assigning it the value 10. A global variable is a variable that is defined outside any function and can be accessed by any part of the code. Then, the code defines a function called "velocity" that takes no parameters and returns the value of "speed" after adding 10 to it. Inside the function, the code uses the global keyword to declare that it wants to use the global variable

"speed", not a local one. A local variable is a variable that is defined inside a function and can only be accessed by that function. The global keyword allows the function to modify the global variable, not just read it. Then, the code adds 10 to the value of "speed" and returns it. Finally, the code calls the function "velocity" and prints the result.

However, the code has a problem. The problem is that the code uses the global keyword inside the function, but not outside. The global keyword is only needed when you want to modify a global variable inside a function, not when you want to create or access it outside a function. If you use the global keyword outside a function, you will get a `SyntaxError` exception, which is an error that occurs when the code does not follow the rules of the Python language. The code does not handle the exception, and therefore it will terminate with an error message.

The expected result of the code is an unhandled exception, because the code uses the global keyword incorrectly. Therefore, the correct answer is A. The code is erroneous and cannot be run.

## NEW QUESTION # 45

What is true about exceptions and debugging? (Select two answers.)

- A. One try-except block may contain more than one except branch.
- B. The default (anonymous) except branch cannot be the last branch in the try-except block.
- C. A tool that allows you to precisely trace program execution is called a debugger.
- D. If some Python code is executed without errors, this proves that there are no errors in it.

**Answer: A,C**

Explanation:

Exceptions and debugging are two important concepts in Python programming that are related to handling and preventing errors. Exceptions are errors that occur when the code cannot be executed properly, such as syntax errors, type errors, index errors, etc. Debugging is the process of finding and fixing errors in the code, using various tools and techniques. Some of the facts about exceptions and debugging are:

\* A tool that allows you to precisely trace program execution is called a debugger. A debugger is a program that can run another program step by step, inspect the values of variables, set breakpoints, evaluate expressions, etc. A debugger can help you find the source and cause of an error, and test possible solutions. Python has a built-in debugger module called `pdb`, which can be used from the command line or within the code. There are also other third-party debuggers available for Python, such as PyCharm, Visual Studio Code, etc<sup>12</sup>

\* If some Python code is executed without errors, this does not prove that there are no errors in it. It only means that the code did not encounter any exceptions that would stop the execution. However, the code may still have logical errors, which are errors that cause the code to produce incorrect or unexpected results. For example, if you write a function that is supposed to calculate the area of a circle, but you use the wrong formula, the code may run without errors, but it will give you the wrong answer. Logical errors are harder to detect and debug than syntax or runtime errors, because they do not generate any error messages. You have to test the code with different inputs and outputs, and compare them with the expected results<sup>34</sup>

\* One try-except block may contain more than one except branch. A try-except block is a way of handling exceptions in Python, by using the keywords `try` and `except`. The `try` block contains the code that may raise an exception, and the `except` block contains the code that will execute if an exception occurs. You can have multiple `except` blocks for different types of exceptions, or for different actions to take. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except ZeroDivisionError: # handle the ZeroDivisionError exception
except: # handle any other exception
This way, you can customize the error handling for different situations, and provide more informative messages or alternative solutions5
```

\* The default (anonymous) `except` branch can be the last branch in the try-except block. The default `except` branch is the one that does not specify any exception type, and it will catch any exception that is not handled by the previous `except` branches. The default `except` branch can be the last branch in the try- `except` block, but it cannot be the first or the only branch. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except: # handle any other exception
This is a valid try-except block, and the default except branch will be the last branch. However, you cannot write a try-except block like this:
```

```
try: # some code that may raise an exception
except: # handle any exception
This is an invalid try-except block, because the default except branch is the only branch, and it will catch all exceptions, even those that are not errors, such as KeyboardInterrupt or SystemExit. This is considered a bad practice, because it may hide or ignore important exceptions that should be handled differently or propagated further. Therefore, you should always specify the exception types that you want to handle, and use the default except branch only as a last resort5 Therefore, the correct answers are A. A tool that allows you to precisely trace program execution is called a debugger. and C. One try-except block may contain more than one except branch.
```
