## CrowdStrike Certified Cloud Specialist Sample Questions (Q72-Q77):

### NEW QUESTION # 72

Which feature of Falcon Horizon allows users to identify exposed cloud services and workloads running without requiring the deployment of a Falcon sensor?

- A. Vulnerability patching orchestration
- B. Deployment of lightweight monitoring agents
- C. Real-time behavioral monitoring
- D. API-driven cloud workload discovery

**Answer: D**

Explanation:

Option A: Patching orchestration is not part of Falcon Horizon's functionality. It focuses on remediation rather than workload discovery or runtime protection.

Option B: While lightweight monitoring agents can provide visibility, this contradicts the requirement of finding workloads without deploying a Falcon sensor. Falcon Horizon's agentless approach eliminates this dependency.

Option C: Real-time behavioral monitoring is a feature of Falcon modules like Falcon Prevent or Falcon Insight, which require sensors to monitor and analyze workload behavior. This is not applicable to environments without sensor deployment.

Option D: Falcon Horizon uses API-driven cloud workload discovery to analyze the state of resources in the cloud environment. By leveraging APIs provided by cloud service providers, Falcon Horizon gathers data on running workloads, exposed services, and misconfigurations without needing to deploy agents or sensors on individual workloads. This approach is efficient and does not require intrusive installation processes.

#### NEW QUESTION # 73

What is the best approach to handle the output of the Falcon CWPP Image Scanning Script to ensure vulnerabilities are addressed effectively?

- A. Ignore the script output in the pipeline and review results manually later.
- B. Automatically fail the pipeline if any vulnerabilities are found, regardless of severity.
- C. Parse the output to filter critical vulnerabilities and send alerts to the security team.
- D. Disable output logging for sensitive image scans to ensure security.

**Answer: C**

Explanation:

Option A: Filtering critical vulnerabilities ensures that the most significant issues are addressed promptly while allowing the pipeline to continue for lower-priority issues. This approach balances security and productivity effectively.

Option B: Disabling logging hinders visibility into vulnerabilities. Security concerns about logs can be mitigated through secure storage and access control rather than disabling logging altogether.

Option C: Ignoring the script output negates the value of integrating the Image Scanning Script into the pipeline. Automated handling ensures vulnerabilities are addressed consistently and promptly.

Option D: Automatically failing the pipeline for all vulnerabilities, including low and informational ones, can disrupt development unnecessarily. The severity of vulnerabilities should be considered before deciding on pipeline actions.

#### NEW QUESTION # 74

Your organization plans to deploy the Falcon Container Sensor in a Kubernetes cluster for enhanced security monitoring. Which of the following is a key requirement for deploying the sensor successfully?

- A. You must disable Kubernetes Role-Based Access Control (RBAC) before deploying the sensor.
- B. All Kubernetes worker nodes must run the CoreOS operating system.
- C. The Falcon Container Sensor requires a privileged DaemonSet for deployment.
- D. The Falcon Container Sensor can only monitor containers running in a specific namespace.

**Answer: C**

Explanation:

Option A: The Falcon Container Sensor uses a privileged DaemonSet to gain access to host-level resources, allowing it to monitor containerized workloads effectively.

Option B: The sensor is compatible with various Linux-based operating systems, not just CoreOS.

Limiting the deployment to CoreOS is unnecessary and incorrect.

Option C: Disabling RBAC is not required and is strongly discouraged as it would reduce the security of the Kubernetes cluster. The Falcon Container Sensor can operate within an RBAC-enabled environment.

Option D: The Falcon Container Sensor monitors all containers across the cluster, not just those in a specific namespace. It operates at the cluster level to provide comprehensive security.

#### NEW QUESTION # 75

You are tasked with reviewing a cloud image configured for deployment in a Kubernetes environment. Which of the following practices identifies a potential misconfiguration that could compromise security?

- A. Utilizing an official base image from a trusted source without scanning it.
- B. Using a multi-stage build to reduce the final image size.
- C. Setting the USER directive to a non-root user in the Dockerfile.
- D. Including hardcoded credentials in the image's environment variables.

**Answer: D**

Explanation:

Option A: Multi-stage builds are a best practice for creating minimal and efficient images by excluding unnecessary build artifacts. This enhances security by reducing the attack surface. It is not a misconfiguration.

Option B: This is a best practice to enhance security. Running the application as a non-root user reduces the impact of a potential compromise, as the attacker's privileges would be limited. This is not a misconfiguration but a security-strengthening measure.

Option C: While using official base images is a good starting point, they can still contain vulnerabilities. Scanning these images for known issues before use is a necessary step to ensure security compliance. Relying solely on their "official" status is a common misconception.

Option D: Hardcoded credentials in environment variables are a critical security misconfiguration.

If the image is shared or deployed in an environment where logs or configurations can be accessed, these credentials can be exposed, leading to unauthorized access. Best practices recommend using a secure secrets management solution instead of hardcoding sensitive information.

## NEW QUESTION # 76

What is the primary function of runtime protection in Falcon Cloud Security?

- **A. To block malicious activity and unauthorized behavior in running workloads.**
- B. To monitor API calls in the Kubernetes control plane for debugging purposes.
- C. To enforce compliance by scanning container images for vulnerabilities prior to deployment.
- D. To provide a backup of the container state for disaster recovery.

**Answer: A**

Explanation:

Option A: Backing up container states is unrelated to runtime protection, which focuses on real-time threat detection and prevention.

Option B: Monitoring API calls is part of Kubernetes control plane security but is not directly related to runtime protection.

Option C: Image scanning for vulnerabilities is a pre-deployment task and does not pertain to runtime protection, which deals with active workloads.

Option D: Runtime protection focuses on safeguarding workloads by detecting and blocking malicious behavior during their execution. It provides continuous monitoring to secure active containerized environments.
