IICRC Water Damage Restoration Technician (WRT) Sample Questions (Q49-Q54):

NEW QUESTION # 49

In order to maximize electrical safety, what shall mitigation equipment include?

- A. A grounded electrical plug
- B. Rubber feet to insulate mechanical components
- C. Water-resistant motor windings
- D. HEPA filters to trap contaminants

Answer: A

Explanation:

The IICRC WRT body of knowledge emphasizes that mitigation equipment used in wet environments must meet electrical safety requirements, including the use of grounded electrical plugs. Grounding provides a safe path for electrical current in the event of a fault, significantly reducing the risk of shock or electrocution.

Water damage restoration environments frequently involve elevated moisture, standing water, and conductive surfaces, all of which increase electrical hazards. The WRT manual reinforces that grounded plugs and properly rated extension cords are essential safety features for air movers, dehumidifiers, and other electrical equipment.

While water-resistant components and insulating features may enhance durability, they do not replace grounding requirements.

HEPA filters address air quality, not electrical safety.

Ensuring grounded equipment aligns with OSHA electrical safety standards and reflects the WRT priority of hazard mitigation before and during restoration work.

NEW QUESTION # 50

What PPE does a restorer need to handle sewage backups?

- A. Respirator, protective body suit, waterproof gloves, and boots
- B. Hard hat, washable coveralls, and rubber boots
- C. Respirator, safety vest, leather boots, and breathable gloves
- D. Respirator, leather gloves, and composite toe boots

Answer: A

Explanation:

The IICRC WRT body of knowledge classifies sewage backups as Category 3 water, which is grossly contaminated and poses serious health risks. Handling such conditions requires enhanced PPE to protect against pathogens, aerosols, and direct contact with contaminants.

The WRT manual specifies that appropriate PPE for sewage losses typically includes a respirator, protective body suit, waterproof or chemical-resistant gloves, and impermeable boots. This ensemble protects the respiratory system, skin, and mucous membranes from exposure.

Leather gloves, breathable gloves, or minimal protective clothing are insufficient because they can absorb contaminants and allow exposure. A hard hat or safety vest may be necessary depending on site conditions, but they do not address biological hazards.

Proper PPE selection is based on hazard assessment and aligns with OSHA requirements. The WRT standard reinforces that worker safety is paramount and that PPE must be suitable for the level of contamination present.

NEW QUESTION # 51

After physically removing bulk water, what has the most significant influence on the time required to dry wet materials?

- A. Fiber saturation point
- B. Rate of condensation
- C. Rate of evaporation
- D. Method of extraction

Answer: C

Explanation:

Once bulk water has been physically removed, the IICRC WRT body of knowledge identifies the rate of evaporation as the most

significant factor influencing drying time. Evaporation is the process by which remaining moisture within materials changes from liquid to vapor and enters the surrounding air.

The WRT curriculum explains that evaporation is controlled by several interrelated variables, including vapor pressure differential, airflow across wet surfaces, surface temperature, and ambient humidity conditions. If evaporation is slow, drying time increases regardless of how effective extraction was initially.

While extraction method plays a critical role in reducing the initial moisture load, it does not control the drying phase once free water has been removed. Similarly, fiber saturation point describes moisture conditions within materials but does not dictate drying speed. Condensation, conversely, inhibits drying and adds moisture.

The WRT body of knowledge reinforces that successful drying requires creating conditions that maximize evaporation while simultaneously removing evaporated moisture through dehumidification or ventilation.

Monitoring evaporation effectiveness is therefore a core responsibility of the restorer during daily inspections.

NEW QUESTION # 52

What is the process used by refrigerant dehumidifiers to remove water from the air?

- A. Adsorption
- B. Absorption
- C. Condensation
- D. Sublimation

Answer: C

Explanation:

Refrigerant dehumidifiers remove moisture from the air through the process of condensation, as outlined in the IICRC WRT body of knowledge. In this process, warm, moist air is drawn across a cold evaporator coil inside the dehumidifier. When the air temperature is reduced below its dew point, water vapor changes phase from a gas to a liquid and condenses on the coil surface.

The collected liquid water then drains into a reservoir or is pumped out of the unit, while the dried air is reheated slightly and discharged back into the drying chamber. This mechanism is fundamental to both conventional refrigerant and low-grain refrigerant (LGR) dehumidifiers.

The WRT curriculum contrasts condensation with adsorption, which is used by desiccant dehumidifiers, and absorption, which involves liquids—not air drying. Sublimation (solid to vapor) is not relevant to restoration drying.

Understanding condensation is essential because refrigerant dehumidifiers rely on sufficient temperature and humidity conditions to function efficiently. The WRT manual highlights operational limits and emphasizes monitoring to ensure that refrigerant systems are appropriate for the environmental conditions present on the job.

NEW QUESTION # 53

What steps should be taken to minimize safety concerns with sagging gypsum board ceilings and promote rapid drying?

- A. Drain, safely remove, and properly dispose
- B. Support to prevent collapse while drying
- C. Drain, properly dry the gypsum, and reinstall
- D. Perforate to increase airflow while drying

Answer: A

Explanation:

The IICRC WRT body of knowledge identifies sagging gypsum board ceilings as a serious structural and safety hazard. Gypsum board loses strength when wet, especially in horizontal installations, and sagging indicates primary damage that cannot be safely reversed.

The WRT manual clearly states that wet gypsum ceilings presenting sagging or collapse risk must be drained, safely removed, and properly disposed of. Attempting to dry sagging ceiling drywall in place is unsafe and inconsistent with professional standards.

Perforation or temporary support does not restore structural integrity and exposes workers and occupants to collapse hazards. Reinstallation is only appropriate after damaged materials are removed and the structure is dried.

This guidance reinforces the WRT principle that life safety always overrides salvage considerations.

Removing compromised ceiling drywall eliminates hazards and allows drying equipment to operate more effectively on remaining structural components.
