### **VMware Advanced VMware Cloud Foundation 9.0 Storage Sample Questions (Q58-Q63):**

### NEW QUESTION # 58

An administrator has been tasked with suggesting storage models for a new VMware Cloud Foundation (VCF) Private Cloud with the following characteristics:

- \* Single VCF Instance with a single Workload Domain.
- \* The VCF Management Workload Domain will consist of a single cluster that uses a highly scalable, integrated storage solution that does not require additional management software or hardware.
- \* The VCF Workload Domain consists of a single Cluster that requires a multiple-tier storage solution consisting of:
  - \* A highly scalable, policy-based storage solution for critical application workloads.
  - \* A file-based storage solution that can scale independently of the cluster for workloads with large data requirements. Which three storage models should the administrator recommend? (Choose three.)

- A. NFS v3 should be the supplemental storage solution for the VCF Workload Domain.
- B. NFS v4.1 should be the principal storage solution for the VCF Management Domain.
- C. iSCSI should be the principal storage solution for the VCF Management Domain.
- D. VMware vSAN should be the principal storage solution for the VCF Management Domain.
- E. iSCSI should be the supplemental storage solution for the VCF Workload Domain.
- F. VMware vSAN should be the principal storage solution for the VCF Workload Domain.

**Answer: A,D,F**

Explanation:

VMware vSAN is the correct principal storage for both the Management Domain and the Workload Domain because it is integrated, policy-based, scalable, and managed directly through VCF and vSphere. The Management Domain requirement explicitly calls for a highly scalable integrated storage solution that does not require additional storage management software or hardware, which aligns with vSAN. The Workload Domain also requires a highly scalable, policy-based storage solution for critical application workloads, which again maps directly to vSAN storage policies and vSAN datastore services. The second workload tier requires file-based storage that can scale independently of the cluster for workloads with large data requirements. NFS v3 is supported as supplemental storage and is appropriate for adding file-based capacity without changing the principal vSAN datastore. iSCSI is supplemental only and does not meet the Management Domain principal storage requirement. NFS v4.1 is not the correct principal storage selection for the Management Domain. ### NEW QUESTION # 59

Which statement accurately defines the fundamental difference in how physical storage devices are organized and utilized in vSAN Original Storage Architecture (OSA) versus Express Storage Architecture (ESA)?

- A. vSAN OSA utilizes standard block-level mapping for virtual disks, whereas vSAN ESA maps virtual machine data directly to individual physical NVMe namespaces bypassing the Distributed Object Manager (DOM).
- B. vSAN ESA requires distinct, dedicated Read-Intensive NVMe drives for capacity and Write-Intensive NVMe drives for cache, whereas OSA supports single-tier hybrid designs.
- C. vSAN OSA rigidly organizes drives into Disk Groups with a dedicated cache tier, whereas vSAN ESA eliminates Disk Groups entirely to form a single-tier Storage Pool where every NVMe device contributes to both performance and capacity.
- D. In vSAN OSA, the hypervisor CPU performs deduplication during the write ingestion phase, while vSAN ESA utilizes hardware offloading on the NVMe drives to handle parity calculations.

**Answer: C**

### NEW QUESTION # 60

An administrator has been tasked with modifying an existing vSAN File Services deployment which uses Active Directory for Kerberos authentication.

Select three settings which can be modified after initially configuring the vSAN File Services. (Choose three.)

- A. Active Directory domain
- B. Organizational Unit
- C. DNS names
- D. Static IP addresses
- E. Primary IP addresses
- F. Active Directory Username

**Answer: C,D,E**

Explanation:

After vSAN File Services has been deployed, the editable settings are primarily related to the File Service domain network configuration. The vSAN File Service workflow allows modification of primary IP addresses, static IP addresses, and DNS names. These values define how the file service endpoints are presented to clients and how file server instances are resolved on the network. The File Service domain can be adjusted by editing the network configuration and adding or removing IP addresses as needed. The Active Directory domain is not treated as a simple post-deployment editable field because changing domain membership can disrupt authentication, permissions, and file-share access. The Active Directory username and Organizational Unit are part of the directory integration and domain-join configuration, but they are not the three standard settings identified for modification after the initial File Services configuration. Therefore, the three modifiable settings are Static IP addresses, Primary IP addresses, and DNS names. Reference topics: vSAN File Service, Edit File Service Domain, File Service Network Configuration, Active Directory Integration.

### NEW QUESTION # 61

A VCF Deployment Specialist is explaining the I/O path of a write operation in a new vSAN ESA cluster to a junior administrator.

...

[Architecture Diagram Concept]

VM (Guest OS) -> vSCSI -> [ ? ] -> Network -> [ ? ] -> Physical NVMe

Drive

...

The specialist must fill in the missing architectural components to show how a write propagates from the compute layer to the storage layer.

Which combination correctly completes the I/O path for a write operation originating on Host A but destined for a replica on Host B?

- A. DOM Owner (Host A) -> Network -> LSOM (Host B) -> DOM Client (Host B)
- **B. DOM Client (Host A) -> Network -> DOM Owner (Host B) -> LSOM (Host B)**
- C. LSOM (Host A) -> Network -> CLOM (Host B) -> DOM Owner (Host B)
- D. CLOM (Host A) -> Network -> DOM Client (Host B) -> LSOM (Host B)

**Answer: B**

### NEW QUESTION # 62

An Operations Engineer is troubleshooting a vSAN ESA cluster. Following a reboot of Host-03, a 50 TB virtual machine object has entered the "Inaccessible" state.

The DOM and LSOM components exist, but the metadata appears desynchronized. The engineer uses the Ruby vSphere Console (RVC) to query the object hierarchy.

...

[RVC Output: vsan.object\_info ~cluster 554350...]

DOM Object: 554350... (State: Inaccessible)

- Component 1: UUID abc... (Host: Host-01, DOM Owner: Active)

- Component 2: UUID def... (Host: Host-02, DOM Owner: Active)

- Component 3: UUID ghi... (Host: Host-03, LSOM State: STALE)

...

How does the architectural handshake between DOM and LSOM function in ESA to validate data integrity when a host reboots, and why is this object inaccessible? (Select all that apply.)

- A. The LSOM on Host-03 must explicitly communicate with the ESXi hypervisor kernel to re-format the NVMe drive before the DOM can re-index the component.
- **B. Recovery requires the DOM to perform a delta-resync, pushing only the changed blocks from the Active components to the LSOM of the STALE component on Host-03.**
- **C. The DOM Owner tracks the Object Configuration Sequence Number (CSN). Host-03 rebooted and missed DOM update generations, so its local LSOM component carries an outdated (STALE) CSN.**
- D. The DOM Client on the compute host will automatically execute an LSOM bypass to read directly from the physical NVMe drives on Host-01 and Host-02.
- **E. Because Host-03 has a STALE component, the DOM denies its voting rights. The object has lost quorum (only 2 of 3 votes are valid), triggering the "Inaccessible" state to prevent reading old data.**

**Answer: B,C,E**
