IT Specialist HTML5 Application Development Sample Questions (Q14-Q19):

NEW QUESTION # 14

What is the effect of applying the CSS float: right property to an image?

- A. It positions the image to the left of the region and wraps text around the top, right, and bottom.
- B. It positions the image to the right and wraps text to the top and bottom.
- C. It positions the image to the right of the region and wraps text around the top, left, and bottom.
- D. It positions the image to the left and displays all of the text to the right of the image.

Answer: C

Explanation:

The correct answer is A. Applying float: right to an image removes the image from the normal inline flow and moves it to the right side of its containing block. Inline content, such as text, is then allowed to flow around the floated image. Because the image is anchored on the right, available text space is primarily on the left side of the image, and the text can continue above, beside, and below the floated region according to the surrounding layout. This is the classic use case for floating images within article-style content, where text wraps around a visual element rather than forcing the image to occupy an entire line. Option B is incomplete because it omits the important left-side wrapping behavior. Option C describes the opposite direction: an image floated left with text appearing to its right. Option D also describes float: left, not float: right.

References/topics: CSS float, floated images, text wrapping, normal flow, content positioning.

NEW QUESTION # 15

Which CSS property defines the sides of an element where other floating elements are not allowed?

- A. display
- B. position
- C. float
- D. clear

Answer: D

Explanation:

The correct property is clear. In CSS layout, float removes an element from the normal inline flow and positions it to the left or right, allowing following content to wrap beside it. The clear property controls whether an element may be positioned next to preceding floated elements or must be moved below them.

MDN defines clear as the property that sets whether an element must be moved below floating elements that precede it. Typical values include left, right, both, and none, allowing the developer to block floats on one or both sides. display controls the formatting behavior of an element, such as block, inline, flex, or grid. float creates the floating behavior; it does not prevent other floats from appearing beside an element. position controls positioning schemes such as static, relative, absolute, fixed, or sticky. Therefore, only clear directly defines the sides where adjacent floating elements are not permitted. References/topics: CSS floats, content flow, clearing floated elements, layout positioning.

NEW QUESTION # 16

You need to define a grid that meets the following requirements:

- * Explicitly sets the width of 6 equal columns of 1 fraction
- * Explicitly sets 5 varied sized rows
- * Defines 15px of space between each grid column
- * Defines 10px between each grid row

Complete the code by selecting the correct option from each drop-down list.

display: grid;

(6, 1fr);

grid-template-rows:
grid-auto-rows:
grid-template-columns:
grid-auto-columns:

repeat

grid-template-rows:
grid-auto-rows:
grid-template-columns:
grid-auto-columns:

10px 15px;

gap:
grid-area:
grid-gap:
span:

Explanation:

display: grid;

grid-template-columns: repeat(6, 1fr);

grid-template-rows: 50px 50px 150px 150px 100px;

grid-gap: 10px 15px;

The correct grid definition starts with `display: grid;`, which turns the element into a CSS Grid container. To explicitly create six equal-width columns, the correct property is `grid-template-columns`, and the most efficient value is `repeat(6, 1fr)`. The `repeat()` function avoids writing `1fr` six separate times, while `1fr` assigns each column one equal fraction of the available grid width. The five row sizes must be explicitly declared with `grid-template-rows`, using the exact varied values shown: `50px 50px 150px 150px 100px`. This creates five rows with fixed pixel heights. For the spacing requirement, `grid-gap: 10px 15px;` is the correct shorthand.

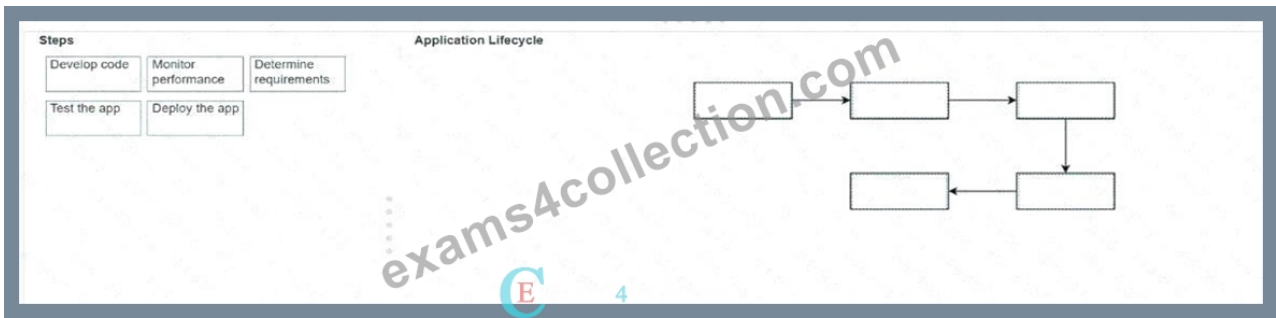

The first value controls the row gap, so rows are separated by 10px; the second value controls the column gap, so columns are separated by 15px. References/topics: CSS Grid containers, explicit grid tracks, `grid-template-columns`, `grid-template-rows`, `repeat()`, fractional units, grid gaps.

NEW QUESTION # 17

You are given the design for an app. The project manager asks you to outline the steps you must take to release and maintain the app.

Move each step from the list on the left to its correct sequence in the application lifecycle on the right.

Note: You will receive partial credit for each correct response.

Answer:

Explanation:

Explanation:

Determine requirements # Develop code # Test the app
#

Monitor performance # Deploy the app

The correct application lifecycle sequence begins with Determine requirements because the team must first define what the app must accomplish, who will use it, and which functional and technical expectations must be satisfied. Since the question states that the design is already provided, the next implementation step is Develop code, where the HTML, CSS, JavaScript, assets, APIs, and app logic are created according to the approved design and requirements. After development, the app must be validated through Test the app.

Testing confirms that the app works correctly, meets requirements, handles user input properly, and does not contain functional defects that would block release. Once testing is complete, the app can be released through Deploy the app, which publishes it to the target environment or makes it available to users. The final operational stage is Monitor performance, where the released app is observed, maintained, updated, and improved based on performance, reliability, defects, and user behavior. References/topics: application lifecycle management, requirements, development, testing, deployment, maintenance.

NEW QUESTION # 18

Match each property to its corresponding value for creating the CSS flexible box layout.

Move each property from the list on the left to the correct value on the right.

Note: You will receive partial credit for each correct match.

The interface shows the following properties and values:

- Properties:** align-items, direction, display, flex-direction, order
- Values:** any, flex | inline-flex, flex-start | flex-end | center, row | row-reverse | column | column-reverse, rtl | ltr
- Property boxes on the right:** Property, Property, Property, Property, Property

Answer:

Explanation:

Properties	Values	
align-items	any	order
direction	flex inline-flex	display
display	flex-start flex-end center	align-items
flex-direction	row row-reverse column column-reverse	flex-direction
order	rtl ltr	direction

Explanation:

Property	Correct Matching Value
align-items	flex-start flex-end center
direction	rtl ltr
display	flex inline-flex
flex-direction	row row-reverse column column-reverse
order	any

A CSS flexible box layout is created by applying the display property to a container with either flex or inline- flex. This establishes the element as a flex container and causes its child elements to become flex items. The flex-direction property defines the direction of the main axis and accepts row, row-reverse, column, and column-reverse, allowing items to flow horizontally, vertically, or in reverse order. The align-items property controls how flex items are aligned along the cross axis, with values such as flex-start, flex-end, and center.

The direction property controls writing direction and accepts ltr for left-to-right text flow or rtl for right-to-left text flow. Finally, order is applied to individual flex items and accepts an integer value, represented here as "any," because any numeric order value can be used to rearrange item display order without changing the document source order. References/topics: CSS flexbox, flex containers, flex items, main axis, cross-axis alignment, writing direction, item ordering.
