Our objective is to provide you with the best learning material to clear the AWS Certified Developer Associate Exam (DVA-C02) (AWS-Certified-Developer-Associate) exam.

Amazon AWS-Developer certification exam is designed for developers who want to demonstrate their ability to develop and maintain applications on the Amazon Web Services (AWS) platform. AWS Certified Developer Associate Exam (DVA-C02) certification validates the skills and knowledge necessary to build, deploy, and manage scalable and secure applications on AWS. The AWS-Developer certification is one of the most popular certifications in the AWS certification family, and it is a great way to showcase your AWS expertise to employers.

Amazon AWS-Developer (AWS Certified Developer - Associate) Exam is a certification exam designed to validate the skills and knowledge of developers who use Amazon Web Services (AWS) to build applications. AWS-Certified-Developer-Associate Exam covers various topics related to AWS services such as compute, storage, database, and networking, as well as application development and deployment. The AWS-Developer exam is an intermediate-level exam and is a prerequisite for the AWS Certified DevOps Engineer Professional certification.

## Amazon AWS Certified Developer Associate Exam (DVA-C02) Sample Questions (Q368-Q373):

### NEW QUESTION # 368

A Developer uses AWS CodeDeploy to automate application deployment that connects to an external MySQL database. The Developer wants to securely access the encrypted secrets, such as API keys and database passwords.

Which of the following solutions would involve the LEAST administrative effort?

- A. Use the Amazon DynamoDB client-side encryption library to save the secrets in DynamoDB and to programmatically access the secrets from EC2 instances.
- B. Use AWS SSM Parameter Store to store the secrets and to programmatically access them by using the IAM role from EC2 instances.
- C. Save the secrets in Amazon S3 with AWS KMS server-side encryption, and use a signed URL to access them by using the IAM role from Amazon EC2 instances.
- D. Use the instance metadata to store the secrets and to programmatically access the secrets from EC2 instances.

**Answer: C**

### NEW QUESTION # 369

A developer is creating an ecommerce workflow in an AWS Step Functions state machine that includes a HTTP Task state. The task passes shipping information and order details to an endpoint.

The developer needs to test the workflow to confirm that the HTTP headers and body are correct and that the responses meet expectations.

- A. Use the data flow simulator to invoke only the HTTP Task. View the request and response data.
- B. Change the log level of the state machine to ALL. Run the state machine.
- C. Use the TestState API to invoke the state machine. Set the inspection level to DEBUG.
- D. Use the TestState API to invoke only the HTTP Task. Set the inspection level to TRACE.

**Answer: D**

Explanation:

Comprehensive and Detailed Step-by-Step Explanation:

To confirm that the HTTP headers, body, and responses meet expectations, you need to test the specific HTTP Task state in isolation and inspect the details.

\* Option A: TestState API with TRACE:

\* The TestState API allows developers to test individual states in a state machine without executing the entire workflow.

\* Setting the inspection level to TRACE provides detailed information about the HTTP request and response, including headers, body, and status codes.

\* This option provides the precise and granular testing required to verify the HTTP Task functionality.

\* Why Other Options Are Incorrect:

\* Option B: The DEBUG inspection level provides less detailed information than TRACE and focuses on general debugging, not a detailed view of HTTP interactions.

\* Option C: Step Functions does not have a "data flow simulator" to test individual tasks; this option is not valid.

\* Option D: Changing the state machine's log level to ALL increases logging granularity for the entire state machine but does not allow isolated testing of a specific HTTP Task.

#### NEW QUESTION # 370

A developer has built a market application that stores pricing data in Amazon DynamoDB with Amazon ElastiCache in front. The prices of items in the market change frequently. Sellers have begun complaining that, after they update the price of an item, the price does not actually change in the product listing. What could be causing this issue?

- A. The cache is not being invalidated when the price of the item is changed.
- B. The DynamoDB table was provisioned with insufficient write capacity.
- C. The DynamoDB table was provisioned with insufficient read capacity.
- D. The price of the item is being retrieved using a write-through ElastiCache cluster.

**Answer: A**

#### NEW QUESTION # 371

A company has three different environments: Development, QA, and Production. The company wants to deploy its code first in the Development environment, then QA, and then Production. Which AWS service can be used to meet this requirement?

- A. Use AWS CodeDeploy to create multiple deployment groups.
- B. Use AWS CodeBuild to create, configure, and deploy multiple build application projects.
- C. Use AWS Data Pipeline to create multiple data pipeline provisions to deploy the application.
- D. Use AWS CodeCommit to create multiple repositories to deploy the application.

**Answer: A**

Explanation:

<https://docs.aws.amazon.com/codedeploy/latest/userguide/deployment-groups.html>

"You can associate more than one deployment group with an application in CodeDeploy. This makes it possible to deploy an application revision to different sets of instances at different times. For example, you might use one deployment group to deploy an application revision to a set of instances tagged Test where you ensure the quality of the code. Next, you deploy the same application revision to a deployment group with instances tagged Staging for additional verification. Finally, when you are ready to release the latest application to customers, you deploy to a deployment group that includes instances tagged Production. "

#### NEW QUESTION # 372

A developer is building a new application on AWS. The application uses an AWS Lambda function that retrieves information from an Amazon DynamoDB table. The developer hard coded the DynamoDB table name into the Lambda function code. The table name might change over time. The developer does not want to modify the Lambda code if the table name changes. Which solution will meet these requirements MOST efficiently?

- A. Store the table name in a file. Store the file in the /tmp folder. Use the SDK for the programming language to retrieve the table name.
- B. Create a Lambda environment variable to store the table name. Use the standard method for the programming language to retrieve the variable.
- C. Create a file to store the table name. Zip the file and upload the file to the Lambda layer. Use the SDK for the programming language to retrieve the table name.
- D. Create a global variable that is outside the handler in the Lambda function to store the table name.

**Answer: C**
