## Linux Foundation Certified GitOps Associate Sample Questions (Q12-Q17):

### NEW QUESTION # 12

In GitOps, how is the Desired State stored?

- A. In a way that enforces mutability and versioning.
- B. In a way that permits direct modifications to live systems.
- C. In a way that retains only the latest version.
- D. In a way that enforces immutability and versioning.

**Answer: D**

Explanation:

The GitOps principle of Versioned and Immutable requires Desired State to be stored in a way that enforces immutability and versioning. This ensures every change is recorded, auditable, and reversible.

"Desired state must be kept in an immutable, version-controlled system. This guarantees a full history of changes and enables safe rollbacks." Thus, the correct answer is D.

References:GitOps Principles (CNCF GitOps Working Group).

### NEW QUESTION # 13

Which of these is an advantage of using a declarative configuration for your Desired State?

- A. Declarative configuration lets you specify complex if/else logic within custom code.
- **B. Using widely adopted community tools for reconciling actual state is less work than maintaining custom imperative scripts.**
- C. Declarative configuration allows you to execute code locally more efficiently to make desired changes to your running system.
- D. Declarative configuration helps you include dynamic scripting that guides an application through a step- by-step process.

**Answer: B**

Explanation:

Declarative configuration describes what the system should look like, not how to achieve it. This enables the use of standard reconciliation tools (like ArgoCD or Flux) to manage the system automatically, removing the burden of writing and maintaining imperative scripts.

"Declarative configuration enables systems to be managed by generic reconciliation tools rather than bespoke scripts, reducing operational overhead and increasing reliability." Thus, the correct answer is B.

References:GitOps Principles (CNCF GitOps Working Group), Declarative Systems.

### NEW QUESTION # 14

In the context of GitOps, what does Desired State refer to?

- A. The state that the system or application was in before any changes were made.
- B. The current state of the system or application.
- C. The state that the system or application will be in after all changes are made.
- **D. The state that the system or application should be in.**

**Answer: D**

Explanation:

The Desired State is the declarative specification stored in Git that defines how the system should look and behave. It is the reference point against which the actual state is continuously reconciled.

"Desired state is the complete declarative specification of a system stored in Git. It defines how the system should be configured and serves as the source of truth for reconciliation." Thus, the correct answer is A.

References:GitOps Terminology (CNCF GitOps Working Group).

### NEW QUESTION # 15

In the context of GitOps, why would you do a rollback?

- A. To test a new feature in a controlled environment.
- **B. To undo a deployment that introduced a critical bug or caused a system failure.**
- C. To improve performance and optimize resource utilization.
- D. To create a backup of the current configuration.

**Answer: B**

Explanation:

In GitOps, rollback is the process of reverting to a previous known-good configuration stored in Git. This is typically done when a deployment introduces a bug, error, or failure that impacts system stability.

"Rollback in GitOps is used to revert to a previous commit representing a stable configuration when the current deployment causes errors or failures." Thus, the correct answer is A.

References:GitOps Principles (CNCF GitOps Working Group), Rollback and Recovery.

## NEW QUESTION # 16

In GitOps, what does it mean to Continuously Reconcile?

- A. Monitor the system for any unauthorized changes and revert them.
- **B. Automatically compare and adjust the system state as needed.**
- C. Regularly update Git repositories with the latest changes from external sources.
- D. Perform regular backups of Git repositories.

**Answer: B**

Explanation:

Continuous reconciliation is another core GitOps principle. It means that software agents (operators or controllers) run loops that continuously observe the live system and compare it against the desired state declared in Git. If any divergence (drift) is found, the agent automatically reconciles the system to match the declared configuration.

"Software agents continuously observe the actual system state and compare it with the desired state declared in Git. If a divergence is detected, the agents automatically reconcile the difference to bring the system back into alignment." This provides automation, consistency, and self-healing, which are hallmarks of GitOps.
