WGU Managing Cloud Security (JY02) Sample Questions (Q42-Q47):

NEW QUESTION # 42

Which of the following is an iterative software development methodology that focuses on achieving customer satisfaction by delivering the software early in the process and welcoming changing requirements from the customer, even late in the process?

- A. Agile
- B. Waterfall
- C. Lean
- D. Spiral

Answer: A

Explanation:

Agile is an iterative software development methodology designed to prioritize customer satisfaction, adaptability, and incremental delivery. Agile teams deliver small, working pieces of software frequently, ensuring feedback is incorporated throughout the process. This flexibility allows late-stage requirement changes to be accommodated without derailing the project.

Waterfall is a sequential approach with limited flexibility. Spiral combines iterative development with risk analysis, but it is not as customer-focused as Agile. Lean emphasizes efficiency and waste reduction but does not center on continuous delivery and adaptability.

Agile frameworks such as Scrum and Kanban embody this philosophy, supporting faster innovation, better collaboration, and responsiveness to evolving business needs.

NEW QUESTION # 43

An organization experienced an unplanned event. As a result, the customers using the web application face a loss of service. What does the incident generated in this situation seek to resolve?

- A. Error
- B. Disruption
- C. Change
- D. Bug

Answer: B

Explanation:

The unplanned event described is a disruption of service. In IT service management frameworks like ITIL, disruptions occur when an incident prevents normal service delivery. The goal of incident management is to restore service quickly and minimize impact on customers.

A bug refers to a software defect, which may cause disruptions but is not synonymous with the event itself.

An error represents a fault, while change refers to deliberate modifications. Only disruption captures the unplanned nature of service unavailability.

Recognizing incidents as disruptions helps organizations apply structured processes such as escalation, root-cause analysis, and communication. It ensures resilience in cloud-based environments where uptime is a key performance indicator and customer trust is closely tied to availability.

NEW QUESTION # 44

An organization wants to ensure that all entities trust any certificate generated internally in the organization. What should be used to generate these certificates?

- A. Individual users' private keys
- B. The organization's certificate authority server
- C. Individual systems' private keys
- D. The organization's certificate repository server

Answer: B

Explanation:

Trust in digital certificates comes from their issuance by a Certificate Authority (CA). A CA is a trusted entity that validates identities and signs certificates. In internal environments, organizations often operate a private CA to issue certificates for users, systems, and services.

If certificates were generated by individual private keys or systems without central authority, there would be no unified trust chain, and validating authenticity across the organization would be impossible. A certificate repository server only distributes certificates but cannot establish trust.

By using an organizational CA server, all certificates are linked to a root of trust. Systems configured to trust the organization's CA will trust any certificate it issues. This allows secure internal communications (TLS, VPN, email signing) and ensures scalability as new services come online. It also supports compliance with enterprise PKI policies.

NEW QUESTION # 45

Which concept focuses on operating highly available workloads in the cloud?

- **A. Reliability**
- B. Resource hierarchy
- C. Security
- D. Operational excellence

Answer: A

Explanation:

Reliability in cloud design ensures workloads can recover quickly from disruptions and continue operating as expected. This concept focuses on high availability, fault tolerance, and disaster recovery. Reliability requires implementing redundancy, backup strategies, and robust monitoring.

Security ensures data protection, operational excellence covers continuous improvement, and resource hierarchy refers to organizational structures, but none focus specifically on availability and resilience.

By prioritizing reliability, organizations design cloud architectures capable of withstanding failures at multiple layers—compute, storage, networking, and even regions. This design principle ensures customer trust and compliance with service-level agreements.

NEW QUESTION # 46

Which tool provides a dedicated environment to contain and analyze malware?

- A. Controller
- **B. Sandbox**
- C. Gateway
- D. Encryption

Answer: B

Explanation:

A sandbox is a controlled, isolated environment used to safely run, observe, and analyze potentially malicious code. In cybersecurity, sandboxes allow analysts to execute malware samples without risking contamination of production systems. This enables identification of malware behavior, persistence techniques, and indicators of compromise.

Encryption protects confidentiality, but does not allow safe execution. Gateways control traffic flow, and controllers manage devices or workloads. Only a sandbox provides the dedicated containment required for malware analysis.

In cloud environments, sandboxing is often implemented at scale to analyze suspicious files or traffic automatically. This practice enhances defenses against zero-day exploits, advanced persistent threats, and polymorphic malware. By preventing malware from escaping, sandboxes provide essential forensic and detection insights without endangering the wider environment.
