CompTIA DataSys+ Certification Exam Sample Questions (Q74-Q79):

NEW QUESTION # 74

Howard is a database designer for an e-commerce website working on creating a table to store customer information. He wants to ensure that each customer can be uniquely identified within the table. Which database concept should Jack use to accomplish this goal?

- A. Foreign Key
- **B. Primary Key**
- C. Relation
- D. Tuple

Answer: B

NEW QUESTION # 75

Which of the following best describes the category of SQL commands required to revoke access to database objects?

- A. TCL
- B. IDDL
- C. IDML
- **D. DCL**

Answer: D

Explanation:

The category of SQL commands that is required to revoke access to database objects is DCL. DCL, or Data Control Language, is a subset of SQL commands that are used to control or manage the access or permissions of users or roles on a database. DCL includes commands such as GRANT and REVOKE. GRANT is a DCL command that is used to grant privileges or roles to users or roles on specific objects in a database, such as tables, views, procedures, etc. REVOKE is a DCL command that is used to revoke privileges or roles from users or roles on specific objects in a database. For example, the following statement uses the REVOKE command to revoke the SELECT privilege from user Alice on table employee:

```
REVOKE SELECT ON employee FROM Alice;
```

The other options are either different categories of SQL commands or not related to SQL commands at all. For example, IDDL is not a valid acronym or category of SQL commands; IDML is not a valid acronym or category of SQL commands; TCL, or Transaction Control Language, is a subset of SQL commands that are used to control or manage transactions on a database, such as committing or rolling back changes. NEW QUESTION # 76

(Before installing a new database instance for an organization, a DBA needs to verify the amount of space, the hardware, and the network resources. Which of the following best describes this process?)

- **A. Checking for database prerequisites**
- B. Provisioning the configuration
- C. Performing patch management
- D. Upgrading the database instance

Answer: A

Explanation:

The correct answer is C. Checking for database prerequisites. According to CompTIA DataSys+ objectives, verifying prerequisites is a critical preparatory step before installing a new database instance.

Database prerequisites refer to the minimum and recommended requirements that must be met to ensure a successful installation and stable operation of the database system.

This process typically includes validating disk space availability, CPU capacity, memory (RAM), and network resources, as well as confirming operating system compatibility, required libraries, kernel parameters, and supporting services. DataSys+ emphasizes that failure to meet prerequisites can lead to installation errors, poor performance, instability, or security vulnerabilities after deployment.

Therefore, DBAs are expected to thoroughly assess the environment before proceeding with installation.

Option A, performing patch management, refers to applying updates and fixes to existing systems to address bugs or security issues. This occurs after software is installed and operational, not before a new database instance is deployed. Option B, upgrading the database instance, involves moving from one version of a database to another and assumes an existing installation is already in place. Option D, provisioning the configuration, focuses on allocating and configuring resources (such as creating instances, users, or storage structures) after prerequisites have been validated.

CompTIA DataSys+ clearly separates environment validation from deployment and configuration activities. Checking prerequisites is a risk-reduction step that ensures the infrastructure can support the database workload and performance expectations from the start. It also supports capacity planning, compliance, and long-term maintainability.

Therefore, the process of verifying space, hardware, and network resources before installing a database instance is best described as checking for database prerequisites, making option C the correct and fully verified answer.

NEW QUESTION # 77

A database analyst notices a query statement is running slowly. Which of the following should the analyst review first?

- A. Table integrity
- B. Database patches
- C. Missing indexes
- D. Code

Answer: C

Explanation:

Missing indexes are a common cause of slow queries, as indexes improve data retrieval speed by allowing efficient searching within tables.

NEW QUESTION # 78

A business analyst queries the same few tables every quarter and does not want to write new SQL code every time. Which of the following would best support the business analyst's needs and allow the database administrator to optimize disk space?

- A. Function
- B. Stored procedure
- C. View
- D. Table

Answer: C
