### WGU Managing Cloud Security (JY02) Sample Questions (Q32-Q37):

#### NEW QUESTION # 32

A governmental data storage organization plans to relocate its primary North American data center to a new property with larger acreage. Which defense should the organization deploy at this location to prevent vehicles from causing harm to the data center?

- A. Cameras
- **B. Bollards**
- C. Locks
- D. Fences

#### Answer: B

Explanation:

Bollards are physical barriers designed to prevent vehicles from ramming into or breaching secure facilities.

They are often placed at entrances, around perimeters, or in front of critical infrastructure like data centers.

Locks, cameras, and fences provide important physical security, but they cannot stop a high-speed vehicle from causing damage. Cameras record activity, fences create boundaries, and locks secure access points, but only bollards physically block or mitigate vehicle attacks.

Governmental and critical infrastructure sites commonly deploy bollards to protect against both accidental collisions and deliberate vehicle-borne attacks. Combined with layered security measures—such as surveillance and fencing—they enhance resilience against physical threats to sensitive data centers.

#### NEW QUESTION # 33

Which phase of software design covers the combination of individual components of developed code and the determination of proper interoperability?

- **A. Testing**
- B. Coding
- C. Training
- D. Planning

#### Answer: A

Explanation:

The phase of software design that integrates individual code components and verifies their interoperability is Testing, specifically integration testing. After developers write and unit-test individual modules, those modules must be combined into a complete system. The testing phase ensures that these modules communicate properly, data flows correctly, and overall functionality meets requirements.

Planning establishes project goals, coding builds individual components, and training prepares users. None of these directly verify interoperability. Testing is critical because even well-functioning components may fail when combined, due to interface mismatches, unexpected data structures, or dependency issues.

Cloud-based systems often integrate microservices, APIs, and third-party services. Testing validates that these distributed components interact seamlessly. Proper testing reduces defects, supports reliability, and ensures a consistent end-user experience. It also aligns with DevOps practices, where continuous integration and automated testing pipelines quickly identify and remediate interoperability issues.

#### NEW QUESTION # 34

An organization that primarily uses a remote work model is reviewing the documentation of various insurance providers to become eligible for cybersecurity insurance. Competitive insurance providers require the organization to implement security controls to ensure only authorized personnel can access the network, data, emails, and other administrative information. Which commonly required

control should the organization implement before applying for cybersecurity insurance from these competitive insurance providers?

- A. Application whitelisting
- B. Multifactor authentication (MFA)
- C. Network segmentation
- D. Trusted platform module (TPM)

**Answer: B**

Explanation:

Multifactor Authentication (MFA) is a commonly mandated control for obtaining cybersecurity insurance.

MFA requires users to present at least two independent factors—something they know (password), something they have (token), or something they are (biometrics). This significantly reduces the risk of unauthorized access due to stolen or weak credentials.

Network segmentation and application whitelisting are valuable, but they are not universal insurance requirements. TPM is a hardware component for securing local devices but does not protect remote access in distributed work models.

By enforcing MFA across VPNs, cloud services, email, and administrative interfaces, organizations demonstrate strong access control measures. Insurance providers recognize MFA as a foundational safeguard, reducing claims risk from credential-based breaches. This makes MFA both a compliance requirement and a best practice.

### NEW QUESTION # 35

Which term describes data elements that, when combined with other information, are used to single out an individual?

- A. Personal details
- B. Direct identifiers
- C. Indirect identifiers
- D. Data subjects

**Answer: C**

Explanation:

Indirect identifiers are pieces of information that may not identify an individual on their own but, when combined with other data, can uniquely identify someone. Examples include birthdate, ZIP code, or gender.

Together, these can re-identify a person, even when names or direct identifiers are removed.

Direct identifiers (such as Social Security numbers) uniquely identify an individual alone. Data subjects are the individuals to whom the data refers, while personal details is too broad and not a formal term.

Understanding indirect identifiers is essential in privacy regulations like GDPR and HIPAA, where pseudonymization or anonymization must account for potential re-identification risks. Safeguarding indirect identifiers reduces the chance of privacy violations and unauthorized profiling.

### NEW QUESTION # 36

An internal developer deploys a new customer information system at a company. The system has an updated graphical interface with new fields. Which type of functional testing ensures that the graphical interface used by employees to input customer data behaves as the employees need it to?

- A. Regression testing
- B. Security testing
- C. Load testing
- D. Acceptance testing

**Answer: D**

Explanation:

Acceptance testing evaluates whether the system meets user requirements and performs as expected in real-world conditions. In this case, employees need the graphical interface to work properly for customer data entry. Acceptance testing confirms usability, accuracy, and functionality from the end user's perspective.

Load testing measures performance under stress, regression testing checks for errors introduced by new changes, and security testing ensures system defenses. These are valuable, but they do not validate end-user satisfaction and workflow alignment.

Acceptance testing is the final validation step before production deployment. It ensures that updates deliver intended business value and user experience. By involving employees in acceptance testing, organizations ensure successful adoption of new systems.
