Amazon AWS Certified Developer - Associate Sample Questions (Q265-Q270):

NEW QUESTION # 265

A developer maintains a critical business application that uses Amazon DynamoDB as the primary data store. The DynamoDB table contains millions of documents and receives 30-60 requests each minute. The developer needs to perform processing in near-real time on the documents when they are added or updated in the DynamoDB table. How can the developer implement this feature with the LEAST amount of change to the existing application code?

- A. Set up a cron job on an Amazon EC2 instance. Run a script every hour to query the table for changes and process the documents.
- B. Enable a DynamoDB stream on the table. Invoke an AWS Lambda function to process the documents.**
- C. Update the application to send a PutEvents request to Amazon EventBridge. Create an EventBridge rule to invoke an AWS Lambda function to process the documents.

- D. Update the application to synchronously process the documents directly after the DynamoDB write

Answer: B

Explanation:

- * DynamoDB Streams: Capture near real-time changes to DynamoDB tables, triggering downstream actions.
- * Lambda for Processing: Lambda functions provide a serverless way to execute code in response to events like DynamoDB Stream updates.
- * Minimal Code Changes: This solution requires the least modifications to the existing application.

NEW QUESTION # 266

A developer is updating an Amazon API Gateway REST API to have a mock endpoint. The developer wants to update the integration request mapping template so the endpoint will respond to mock integration requests with specific HTTP status codes based on various conditions.

- A. `{ if $context.integration.status } "statusCode": 200 else "statusCode": 500 end }`
- B. `{ if $input.params('integration') == "mock" } "statusCode": 404 else "statusCode": 500 end }`
- C. `{ if $input.params('scope') == "internal" } "statusCode": 200 else "statusCode": 500 end }`
- D. `{ if $input.path("integration") } "statusCode": 200 else "statusCode": 404 end }`

Answer: A

Explanation:

Comprehensive Detailed Step by Step Explanation with All AWS Developer References:

In this scenario, the developer is configuring a mock integration in API Gateway. The integration request mapping template allows you to map the incoming request data to a format that the API expects. For mock integration, it's common to return specific HTTP status codes based on the conditions.

Using `$context.integration.status`: The `$context.integration.status` variable refers to the status of the API Gateway integration, which is useful for generating responses based on the condition. Option D correctly uses this variable to determine the HTTP status code, returning 200 for a successful mock request or 500 for a failure.

Alternatives:

Options A, B, and C do not use the correct context variables for handling mock integrations. These options would not return the correct status codes based on the actual integration status.

NEW QUESTION # 267

A developer needs to deploy the code for a new application on an AWS Lambda function. The application needs a dependency file that is 500 MB to run the business logic.

Which solution will meet these requirements?

- A. Package the application code and dependencies into a container image. Push the image to an Amazon Elastic Container Registry (Amazon ECR) repository. Deploy the image to the Lambda function.
- B. Compress the application code and dependencies into a .zip file. Directly upload the .zip file as a deployment package for the Lambda function instead of copying the code.
- C. Compress the application code and dependencies into a .zip file. Upload the .zip file to an Amazon S3 bucket. Configure the Lambda function to run the code from the .zip file in the S3 bucket.
- D. Package the application code and dependencies into a container image. Upload the image to an Amazon S3 bucket. Configure the Lambda function to run the code in the image.

Answer: A

NEW QUESTION # 268

A developer is updating the code for an AWS Lambda function to add new capabilities. The Lambda function has version aliases for

production and development environments that run separate versions of the function. The developer needs to configure a staging environment for the Lambda function to handle invocations to both the development version and the production version. Which solution will meet these requirements?

- A. Create a weighted alias that references the production version of the function and the updated version of the function.
- B. Use AWS CodeDeploy to create a linear traffic shifting deployment
- C. Create a tag for the Lambda function that contains the production version and updated version of the code.
- D. Add a Network Load Balancer. Add the production version of the function and updated version of the function as targets.

Answer: A

NEW QUESTION # 269

A developer designed an application on an Amazon EC2 instance. The application makes API requests to objects in an Amazon S3 bucket. Which combination of steps will ensure that the application makes the API requests in the MOST secure manner? (Select TWO.)

- A. Create an IAM role that has permissions to the S3 bucket. Assign the role to an IAM group.
- B. Store the credentials of the IAM user in the environment variables on the EC2 instance.
- C. Create an IAM role that has permissions to the S3 bucket.
- D. Create an IAM user that has permissions to the S3 bucket. Add the user to an IAM group.
- E. Add the IAM role to an instance profile. Attach the instance profile to the EC2 instance.

Answer: C,E

Explanation:

IAM Roles for EC2: IAM roles are the recommended way to provide AWS credentials to applications running on EC2 instances. Here's how this works:

You create an IAM role with the necessary permissions to access the target S3 bucket.

You create an instance profile and associate the IAM role with this profile.

When launching the EC2 instance, you attach this instance profile.

Temporary Security Credentials: When the application on the EC2 instance needs to access S3, it doesn't directly use access keys. Instead, the AWS SDK running on the instance retrieves temporary security credentials associated with the role. These are rotated automatically by AWS.
