VTNE試験合格攻略 & VTNE練習問題

Fast2testはあなたが次のAAVSBのVTNE認定試験に合格するように最も信頼できるトレーニングツールを提供します。Fast2testのAAVSBのVTNE勉強資料は問題と解答を含めています。それは実践の検査に合格したソフトですから、全ての関連するIT認証に満たすことができます。

AAVSB Veterinary Technician National Exam 認定 VTNE 試験問題 (Q211-Q216):

質問 # 211

A hospitalized patient will bark and not willingly allow someone to put on a leash while in the cage. He is perfectly friendly out of the enclosure but has lunged when in the cage. He is fine if you let him exit the cage on his own and then wags his tail and willingly lets you put the leash on.

What warning should this pet receive on a cage card and as a flag in the cart?

- A. Fearful
- **B. Cage aggressive**
- C. Fear-related aggression
- D. Aggressive

正解: B

解説:

While one would need to know the pet and monitor the behaviors, by the description, the pet sounds like he is cage aggressive. This is either because he is fearful or for some other reason that isn't known by this brief introduction to the pet's behavior. However, we do not want to give the dog a fearful or aggressive label. Instead, we want to describe the behavior and not label the pet as overall bad.

This dog is clearly friendly outside the crate environment. Stating cage aggressive with a qualifier, such as open the door and leash out of the cage, or caution when reaching into the crate, shows a bit about the dog's behavior but doesn't label him as aggressive. He doesn't require a muzzle or the added stress of attempting to get him out of the cage. Labeling him simply as cage aggressive with a description of how to handle him changes the way someone who doesn't know the dog may handle him in the future. If they just saw aggressive, this heightens the human's stress level, which dogs sense and can lead to other unwanted behaviors.

質問 # 212

When capturing cattle, why is it important to know where their point of balance is located?

- A. It helps the handler know when to call for help
- B. It reduces the chances of the handler getting hurt
- C. It keeps the animal from falling during the capture
- **D. It helps the handler understand how to move the animal in the desired direction**

正解: D

解説:

When attempting to capture and restrain cattle, it is helpful to know the point of balance of cattle is the shoulder. This means that when the handler wants the animal to move in a certain direction, the location of the animal's shoulder is the most important factor. The handler can enter the animal's flight zone and approach the shoulder as a way of moving the animal in the opposite direction. Knowing where an animal's point of balance is located is not important in keeping the cow from falling or ensuring the handler's physical safety.

質問 # 213

Which of the following examples describes maladaptive pain?

- A. An owner reports licking at the incision by a young male dog that was neutered today
- B. A dog sustained a ruptured cruciate ligament while playing at the park this morning and is not bearing weight on the leg this afternoon
- **C. An owner calls because her elderly cat with chronic lumbar spinal arthritis resents light petting over her shoulder in the past two days**
- D. A horse returned limping from his paddock overnight with a laceration over his pastern

正解: C

解説:

Maladaptive pain has no protective benefit to the patient. The pain has persisted beyond normal healing or is in excess of residual disease. The time it takes for maladaptive pain to develop varies with each individual, how long the pain has been present without relief, and other underlying factors.

Types of maladaptive pain include: perceived pain intensity in excess of stimuli, pain persisting longer than expected for stimuli, or pain extended to other tissues that are not injured.

The other examples provided are either acute or adaptive ("good pain").

質問 # 214

You are asked to assist in managing a wound sustained by a hit by a car. The dog was stabilized overnight, and a light bandage was placed over the wound until the pet was stable enough to address the wound fully. The veterinarian advises that because the wound is open, contaminated, and happened over six hours ago, they plan to allow it to heal by second intention, at least initially, to permit debridement before attempting a primary closure.

All of the following are appropriate indications for using medicinal honey (Manuka honey) on the wound, except:

- A. Bandages should remain in place for a minimum of 48 hours to permit effect
- B. Provides an energy source for the healing cells
- C. The inflammatory phase of wound healing
- D. Creates a hypertonic environment

正解: A

解説:

Research shows that medicinal honey confers several benefits when applied to bandages for wound healing via second intention (non-surgical closure). These include:

*It creates a hypertonic environment.

*It provides energy sources for any healing cells.

*It aids in debridement.

*It aids in granulation formation. However, once granulation is present (no longer the inflammatory phase), discontinue use as it may permit desiccation or traumatize the newly growing tissue.

*It is beneficial in burn healing.

*It can be placed directly on the wound or impregnated/placed onto the bandage material.

*It has a low pH.

*It has hydrogen peroxide activity.

*Its methylglyoxal component aids in antibacterial activity.

*It has antiinflammatory activity.

*It has antioxidant properties.

*It promotes debridement.

Please do not use medicinal honey on clean, granulating wounds. Because honey is acidic, once the inflammatory phase has ended and the granulation phase is ongoing, using honey could lead to overgranulation.

Make sure only medical-grade honey is used, as store-bought commercial honey could have bacterial contamination.

When using honey with a bandage, bandage changes must take place every 24 hours.

質問 # 215

A valuable high-producing cow presents 26 hours after parturition. The farmer noticed that the cow was still intermittently showing signs of uterine contraction once the calf was delivered. He then saw that tissue was everting through the cervix and knew that there was a problem. He witnessed the calf nursing and called the hospital immediately. You take the call and are concerned the cow may have a uterine prolapse. You advise the client that the uterus needs to be placed back into the proper position and head to the farm with the veterinarian. Upon arrival, the veterinarian confirms uterine prolapse and requests you get her ready for surgical intervention. You start to prepare the cow for surgery and place her in what position?

- A. Any of these
- B. Left lateral recumbency
- C. Sternal recumbency
- D. Dorsal recumbency

正解: C

解説:

Cows needing uterine replacement can be placed either in sternal recumbency with the hind legs stretched behind them, which cranioventrally tilts the pelvis, making replacement easier, or left standing. Regardless, they will receive epidural anesthesia to control pain and relax the musculature in the area of concern.

Once in position, the uterus is cleaned with water and a mild aseptic solution. This removes debris and contamination. Any edema (swelling) can be reduced via manual massage during the initial attempts to replace the tissue.

Suppose the uterus is manually restored to the physiologic position. In that case, oxytocin should be administered to assist in the

process of uterine involution. If the cow is ambulatory and remains so, this may be all that she needs. However, if she was recumbent on presentation or compromised in other ways, a vulvar retention suture may be warranted. Prognosis depends on how quickly the problem is detected, the degree of contamination and damage, and the state of the dam at presentation.
