IBM MQ v9.4 Administrator - Professional Sample Questions (Q104-Q109):

NEW QUESTION # 104

In IBM MQ, administrators often configure multiple queue managers to work together for high availability. Which explanation correctly details how multi-instance queue managers function, how they provide failover, and what differences exist compared to clustering?

- A. Multi-instance queue managers require manual intervention to switch to the standby instance, while clustering provides automatic failover.
- B. Multi-instance queue managers operate independently without sharing state, and clustering automatically merges queues into a single logical queue.
- C. Multi-instance queue managers maintain a primary and standby instance sharing the same storage, automatically failing over if the primary fails, whereas clustering connects multiple independent queue managers to enable load balancing and routing.
- D. Multi-instance queue managers replicate all messages in real-time to every other queue manager, while clusters only

monitor message flow.

Answer: C

Explanation:

Multi-instance queue managers provide high availability by maintaining a standby instance that takes over automatically if the primary fails, while clustering offers routing, load balancing, and high availability across multiple independent queue managers.

NEW QUESTION # 105

IBM MQ provides different types of channels to enable communication between clients and servers or between queue managers. Which type of channel is specifically designed for application programs to connect to a queue manager over a network, and how does it differ from other channel types in terms of usage and configuration?

- A. Message channel (MQCHL), which directly transfers messages between queues on the same queue manager
- B. Sender-receiver (SDR/RCVR) channel, used for internal message storage within a single queue manager
- **C. Server-connection (SVRCONN) channel, designed for client applications to connect to the queue manager remotely over TCP/IP**
- D. Cluster channel, which is used to replicate queue definitions across different queue managers without message transfer

Answer: C

Explanation:

Server-connection channels allow client applications to connect remotely to a queue manager over TCP/IP, unlike sender/receiver channels that handle inter-queue manager message transfer.

NEW QUESTION # 106

In a logistics company, several microservices consume order messages from an IBM MQ queue. If one of the consumer services fails to process a message repeatedly due to application errors, administrators want the message to be moved automatically to a holding area for later inspection. Which IBM MQ feature addresses this requirement?

- A. Segmentation and reassembly
- B. Temporary dynamic queue
- **C. Backout queue with backout threshold**
- D. Message grouping for ordered delivery

Answer: C

Explanation:

Backout queues store messages that repeatedly fail processing beyond a set threshold, allowing inspection without blocking other message flows.

NEW QUESTION # 107

In IBM MQ, when a large retail organization needs to integrate point-of-sale systems, inventory databases, and supplier applications, the administrators want to ensure that messages are not only reliably delivered but also that they can be recovered in case of system crash by replaying from logs without requiring application-level intervention. Which configuration provides this capability?

- A. Using non-persistent queues with high throughput settings
- B. Allowing only application-controlled checkpoints for message recovery
- **C. Enabling persistent messaging with recovery logs and write-ahead logging mechanism**
- D. Using temporary queues with manual backup scripts for replay

Answer: C

Explanation:

Persistent messaging with write-ahead logging ensures that messages can be recovered and replayed by the queue manager after a crash, eliminating reliance on application-level recovery.

NEW QUESTION # 108

In IBM MQ, application programs can connect to a queue manager using client or bindings mode. What is the difference between these two connection modes in terms of resource utilization, security, and message throughput, and why might an enterprise choose one mode over the other for high-performance environments?

- A. Client mode connects over the network using SVRCONN channels, providing flexibility but slightly higher network latency, while bindings mode runs within the same system as the queue manager, offering higher throughput and lower latency
- B. Client mode stores all messages locally before delivery, while bindings mode sends messages directly to remote queues
- C. Client mode encrypts all messages automatically, whereas bindings mode does not support encryption
- D. Bindings mode allows multiple queue managers to connect automatically, while client mode does not

Answer: A

Explanation:

Bindings mode provides faster local communication with low latency, while client mode is flexible for remote connections using SVRCONN channels. Enterprises choose based on performance and deployment architecture.
