WGU Managing Cloud Security (JY02) Sample Questions (Q54-Q59):

NEW QUESTION # 54

Which methodology encompasses conducting tests around the interaction of end users with new code that is intended for a patch?

- A. Functional testing
- B. Full testing
- C. Tabletop testing
- D. Nonfunctional testing

Answer: A

Explanation:

Functional testing validates that new or updated code performs correctly from the end user's perspective.

This type of testing ensures that the patch delivers intended results without introducing errors. It focuses on verifying user interactions, workflows, and outputs.

Full testing may cover all aspects, but it is broader than necessary. Nonfunctional testing evaluates performance, scalability, or usability, not direct functionality. Tabletop testing is a discussion-based exercise, often used for incident response.

Functional testing ensures customer satisfaction by aligning patches with expected system behavior. It is a core component of Agile and DevOps pipelines, where user experience and rapid delivery are prioritized.

NEW QUESTION # 55

In most redundant array of independent disks (RAID) configurations, data is stored across different disks. Which method of storing data is described?

- A. Striping
- B. Mapping
- C. Crypto-shredding
- D. Archiving

Answer: A

Explanation:

The method described is striping, which is a technique used in RAID configurations to improve performance and distribute risk.

Striping involves splitting data into smaller segments and writing those segments across multiple disks simultaneously. For example, if a file is divided into four parts, each part is written to a separate disk in the RAID array.

This parallelism enhances input/output (I/O) performance because multiple drives can be accessed at once. It also provides resilience depending on the RAID level. While striping by itself (RAID 0) increases performance but not redundancy, when combined with mirroring or parity (e.g., RAID 5 or RAID 10), it offers both speed and fault tolerance.

The purpose of striping in the data management context is to optimize how data is stored, accessed, and protected. It is fundamentally different from archiving, mapping, or crypto-shredding, as those serve different objectives (long-term storage, logical placement, or secure deletion). Striping is central to high-performance storage systems and supports availability in mission-critical environments.

NEW QUESTION # 56

Which means of access management is used to determine whether someone is a legitimate user?

- A. Policy management
- **B. Authentication**
- C. Federation
- D. Authorization

Answer: B

Explanation:

Authentication is the access management process used to determine whether someone is a legitimate user.

Managing Cloud documentation explains that authentication verifies identity by validating credentials such as passwords, certificates, tokens, or biometric data.

This process answers the question, "Who are you?" before granting access to systems or services. Strong authentication mechanisms are critical in cloud environments due to remote access, shared infrastructure, and internet exposure.

Authorization determines what an authenticated user is allowed to do, federation enables identity sharing across systems, and policy management defines rules. Therefore, authentication is the correct answer.

NEW QUESTION # 57

Which design pillar encompasses the ability to support development and run workloads effectively, gain insights into operations, and continuously improve supporting processes to deliver business value?

- **A. Operational excellence**
- B. Reliability
- C. Sustainability
- D. Performance efficiency

Answer: A

Explanation:

The Operational Excellence pillar emphasizes practices that allow organizations to develop, deploy, and operate workloads effectively. It includes monitoring operations, responding to incidents, and continuously improving processes. By embedding feedback loops, organizations enhance agility and ensure that technology supports business value.

Performance efficiency deals with using computing resources efficiently, reliability ensures system availability, and sustainability focuses on environmental responsibility. While important, these do not encompass the process-driven improvements at the heart of operational excellence.

Operational excellence ensures that organizations can adapt quickly to changes, implement automation, and drive consistent improvements across cloud workloads. It is a key principle in cloud frameworks like AWS Well-Architected, Microsoft CAF, and Google's Reliability Engineering practices.

NEW QUESTION # 58

An organization is planning for an upcoming Payment Card Industry Data Security Standard (PCI DSS) audit and wants to ensure that only relevant files are included in the audit materials. Which process should the organization use to ensure that the relevant files are identified?

- A. Anonymization
- B. Normalization
- C. Tokenization
- **D. Categorization**

Answer: D

Explanation:

Categorization is the process of systematically identifying and classifying files according to content and relevance. In preparation for a PCI DSS audit, it is critical to identify which files fall within scope—those that contain cardholder data or impact its security.

Normalization adjusts data format, tokenization substitutes sensitive data with tokens, and anonymization removes identifiers. While useful, none directly address the task of isolating "relevant files" for audit.

Categorization ensures that files are grouped correctly, allowing auditors to focus on the proper scope and preventing unnecessary exposure of unrelated data.

This step aligns with PCI DSS requirements that limit scope to systems and data directly affecting cardholder data security. Proper categorization streamlines audits and demonstrates effective data governance.
