Palo Alto Networks XSOAR Engineer Sample Questions (Q63-Q68):

NEW QUESTION # 63
A playbook task is set up to run an integration command that takes no input and which outputs information to the context. The integration has several instances configured.
Which action will ensure the integration command only runs once?.

- A. Specify the using- parameter to target a specific integration instance to run.
- B. Specify the runlimit= parameter to limit the number of times a specific command will run.
- C. Click on Performance # Run Limits to specify the maximum run count before the task exits.
- D. Click on Advanced Options # Limits to specify the minimum / maximum run limits for a command.

Answer: A

Explanation:
When an integration has multiple instances configured, XSOAR's playbook engine attempts to execute the command once per available instance unless directed otherwise. This behavior is described in the Playbook Task Execution Model within the Admin

Guide. To prevent multiple executions, the engineer must explicitly specify which integration instance the command should use. Playbook tasks include a "Using" drop-down (the "using=" parameter in CLI form), which binds the task to a particular instance. Once set, XSOAR will run the command only on that selected instance, ensuring it does not loop through all available instances. The limits settings in Advanced Options or Performance sections control retry behavior or error handling, not instance selection. The "runlimit" parameter is used for limiting iterative loops or repeated command execution inside playbooks, not for controlling multi-instance execution.
Thus, to ensure the integration command executes only once, the engineer must specify the using=instance_name, making option A the correct answer.
