## Pure Storage Pure Certified FlashArray Storage Professional Sample Questions (Q52-Q57):

### NEW QUESTION # 52

An administrator needs a comparison of FA File performance across multiple arrays. What Pure1 Manage report will provide the best results?

- A. Array Performance
- **B. File Systems Performance**
- C. Overview Dashboard

**Answer: B**

**Explanation:**

**Pure1 Manage Capabilities:** Pure1 is a SaaS-based platform that provides a "single pane of glass" view across an entire fleet of FlashArrays. It excels at aggregating metrics that are otherwise siloed on individual arrays.

**Specialized File Metrics:** Because FlashArray File (FA File) operates as a specific service layer within Purity, its performance metrics (NFS/SMB latency, throughput, and IOPS) are tracked separately from traditional block storage.

**The File Systems Performance Report:** This specific report/view in Pure1 allows administrators to:

Select multiple file systems residing on different arrays.

Overlay their performance graphs to identify trends or outliers.

Filter by specific protocol (NFS vs. SMB) to see how different workloads are behaving across the infrastructure.

Why Options B and C are less ideal:

**Overview Dashboard:** While great for a "health at a glance" check (showing total capacity and high-level alerts), it does not provide the granular, side-by-side performance comparison required for a deep-dive analysis.

**Array Performance:** This report typically shows the total load on the controllers. While this includes file traffic, it often aggregates it with block traffic, making it difficult to isolate how the file services specifically are performing across the fleet.

**Analytical Advantage:** Using the File Systems Performance report allows the administrator to correlate performance spikes with specific file-level events, such as a large backup job or a high-intensity data migration occurring on one array versus another.

**NEW QUESTION # 53**

An administrator is running commands to verify NVME/TCP connectivity from the hosts to the FlashArray. They use the command `ping -M do -s 8972 <ip_addr>` from the initiator and it fails.

What should the administrator do to resolve the issue?

- A. Engage support to enable NVME/ TCP services.
- **B. Check the MTU of 9000 is set on each hop to the FA.**
- C. Run the command from the target.

**Answer: B**

**Explanation:**

When configuring NVME/TCP (or iSCSI) for optimal performance on a Pure Storage FlashArray, configuring Jumbo Frames (an MTU of 9000) end-to-end is a standard best practice.

The command `ping -M do -s 8972 <ip_addr>` is specifically used to verify Jumbo Frame configuration across the network.

The `-M do` flag sets the "Do Not Fragment" (DF) bit, meaning the network is not allowed to break the packet into smaller pieces.

The `-s 8972` flag sets the ICMP data payload to 8972 bytes. When you add the standard 8-byte ICMP header and the 20-byte IP header, the total packet size equals exactly 9000 bytes.

If this ping command fails, it indicates that somewhere along the network path between the host (initiator) and the FlashArray (target), a switch port, router, or network interface is not configured to support an MTU of 9000. The packet is being dropped because it is too large and cannot be fragmented. The administrator must verify the MTU settings on every network hop (switches, routers, and host NICs) to resolve the issue.

Here is why the other options are incorrect:

Engage support to enable NVME/ TCP services (A): The failure of a Jumbo Frame ping test is a Layer 2/Layer 3 network configuration issue, not an indicator that the NVMe/TCP storage protocol service is disabled on the array.

Run the command from the target (C): While pinging from the FlashArray back to the host is a valid secondary troubleshooting step, it will likely also fail if the network path doesn't support Jumbo Frames. The actual resolution is to fix the MTU on the network hops.

**NEW QUESTION # 54**

What is the Pure Storage recommended Maximum Transmission Unit (MTU) size for the replication ports on a FlashArray?

- A. 0
- **B. 1**
- C. 2

**Answer: B**

**Explanation:**

**Understanding MTU:** The Maximum Transmission Unit (MTU) defines the largest size of a packet or frame that can be sent in a single network transaction. The standard Ethernet MTU is 1500 bytes. Anything larger than 1500 bytes is referred to as a Jumbo

Frame.

Replication Efficiency: Replication involves moving large amounts of data between arrays. Using standard 1500-byte frames results in higher overhead because the CPU must process a larger number of headers for the same amount of data. By increasing the MTU, the FlashArray can pack more data into each frame, reducing CPU interrupts and improving overall throughput.

The Pure Recommendation: Pure Storage specifically recommends an MTU of 9000 for both iSCSI and Replication traffic. This is the industry standard for Jumbo Frames that balances efficiency with compatibility across most enterprise-grade switches.

Configuration Requirements: It is critical to remember that MTU must be configured end-to-end. For an MTU of 9000 to work on the replication ports:

The FlashArray replication ports must be set to 9000.

The network switches along the path (and any routers/ISLs) must support and be configured for at least 9000.

The target array's replication ports must also be set to 9000.

Why 9216 (Option A) is incorrect: While some switches support a "Baby Giant" or slightly larger MTU like 9216 to account for VLAN tagging overhead, Pure's internal and best practice documentation specifically points to 9000 as the standard setting for the array's interface.

### NEW QUESTION # 55

What does an asynchronous blackout window prevent?

- A. New replication transfers that started before the blackout window.
- B. In progress transfers that started before the blackout window.
- C. New replication transfers from starting during the blackout window.

**Answer: C**

Explanation:

Definition of a Blackout Window: In Purity//FA, a Blackout Window is a scheduled period during which asynchronous replication is suspended. This is typically used by administrators to preserve WAN bandwidth during peak business hours or to prevent replication traffic from competing with high-priority local workloads (like a massive database batch job).

The "In-Progress" Rule: One of the most important characteristics of a blackout window is that it is non-disruptive to active transfers. If a replication job started at 7:55 AM and the blackout window begins at 8:00 AM, Purity will allow that specific transfer to continue until it finishes.

The Prevention Mechanism: Once the clock hits the start of the blackout window, the replication scheduler is effectively "paused." No new snapshots will be queued for transfer, and no new replication sessions will be initiated until the window expires.

Why Option A is incorrect: Purity does not kill active transfers. Abruptly stopping a transfer would waste the bandwidth already consumed and require the entire delta-set to be re-calculated or re-sent later.

Why Option B is incorrect: The phrasing is logically inconsistent; you cannot prevent something that "started before" the window from being "new" during the window.

Best Practice: When configuring blackout windows, ensure that the "clear" time (the time between windows) is long enough to allow the array to catch up on the snapshots that were queued during the blackout, otherwise, you risk triggering Alert 51 (Replication Delayed).

### NEW QUESTION # 56

A FlashArray administrator has created a 1PB volume and wants to resize it to 1TB, but accidentally sets the new size to 1GB.

How can the administrator recover the potentially truncated data?

- A. Revert the volume to the original size.
- B. Create a snapshot of the current volume and restore data from the copy.
- C. Copy from the auto-generated destroyed snapshot.

**Answer: C**

Explanation:

Purity Safety Mechanism: In Pure Storage Purity, volume resizing-specifically downsizing-is a destructive operation because it can lead to data truncation. To protect against human error (like the one described in the scenario), Purity automatically creates a "pre-resize" snapshot of the volume before the change is committed.

The "Destroyed" Snapshot: When a volume is shrunk, Purity generates a snapshot of the volume in its state immediately before the shrink operation. This snapshot is placed in the Destroyed (or "Pending Eradication") bucket.

Recovery Process: To recover the data, the administrator does not simply "resize back up" (Option C), as the data beyond the 1GB mark may have already been unmappped or treated as truncated by the host file system. Instead, the administrator should locate the

auto-generated snapshot in the Destroyed volumes/snapshots section, "recover" it to make it active again, and then either copy that snapshot to a new volume or overwrite the truncated volume from that snapshot.

SafeMode Integration: If SafeMode is enabled, these auto-generated snapshots are even more secure, as they cannot be manually eradicated before the timer expires, ensuring a guaranteed recovery point for accidental shrinks.

Why Option C is incorrect: Increasing the size of a volume back to 1 TB (or 1PB) does not automatically restore the data that was logically removed or truncated when the volume was set to 1GB; the host file system would still see the data as corrupted or missing.
