

Pass Guaranteed Newest Python Institute - PCEP-30-02 - PCEP - Certified Entry-Level Python Programmer New Soft Simulations

P.S. Free & New PCEP-30-02 dumps are available on Google Drive shared by Exam-Killer: <https://drive.google.com/open?id=1H8UHLfâPSrS5n5iz3ADFPNnkX9X48Pi2>

The PCEP-30-02 learning materials from our company are very convenient for all people, including the convenient buying process, the download way and the study process and so on. Upon completion of your payment on our PCEP-30-02 exam questions, you will receive the email from us in several minutes, and then you will have the right to use the PCEP-30-02 Test Guide from our company. In addition, there are three different versions for all people to choose: PDF, Soft and APP versions. According to your actual situation, you can choose the suitable version from our PCEP-30-02 study question.

Python Institute PCEP-30-02 Exam Syllabus Topics:

Topic	Details
Topic 1	<ul style="list-style-type: none">• Computer Programming Fundamentals: This section of the exam covers fundamental concepts such as interpreters, compilers, syntax, and semantics. It covers Python basics: keywords, instructions, indentation, comments in addition to Booleans, integers, floats, strings, and Variables, and naming conventions. Finally, it covers arithmetic, string, assignment, bitwise, Boolean, relational, and Input• output operations.
Topic 2	<ul style="list-style-type: none">• Data Collections: In this section, the focus is on list construction, indexing, slicing, methods, and comprehensions; it covers Tuples, Dictionaries, and Strings.
Topic 3	<ul style="list-style-type: none">• parameters, arguments, and scopes. It also covers Recursion, Exception hierarchy, Exception handling, etc.
Topic 4	<ul style="list-style-type: none">• Functions and Exceptions: This part of the exam covers the definition of function and invocation

PCEP-30-02 New Soft Simulations - Your Powerful Weapon to Pass PCEP - Certified Entry-Level Python Programmer

The Web-Based Python Institute PCEP-30-02 practice test evaluates your PCEP - Certified Entry-Level Python Programmer exam preparation with its self-assessment features. With this computer-based program, you may automate the entire Python Institute exam testing procedure. The web-based Python Institute PCEP-30-02 practice test elegantly designed interface is compatible with all browsers, including Internet Explorer, Safari, Opera, Google Chrome, and Mozilla Firefox. It will make practice and preparation for the Python Institute PCEP-30-02 Exam more intelligent, quick, and simple. So, you can be confident that you will find all you need to know to pass the Python Institute PCEP-30-02 exam questions on the first try.

Python Institute PCEP - Certified Entry-Level Python Programmer Sample Questions (Q29-Q34):

NEW QUESTION # 29

Drag and drop the conditional expressions to obtain a code which outputs * to the screen.
(Note: some code boxes will not be used.)

```
pool = 42 - 1 // 2
if :
    print('*')
elif :
    print('****')
else:
    print('****')
```

Answer:

Explanation:

pool => 0

pool < 0

pool > 0

```

pool = 42 - 1 // 2
pool > 0
print("*")
elif pool < 0
    print("***")
else:
    print("****")

```

PYTHON INSTITUTE
Open Education & Development Group

Explanation:

pool = 0

pool => 0

```

pool = 42 - 1 // 2
if pool > 0:
    print("*")
elif pool < 0:
    print("***")
else:
    print("****")

```

PYTHON INSTITUTE
Open Education & Development Group

One possible way to drag and drop the conditional expressions to obtain a code which outputs * to the screen is:

```

if pool > 0:
    print("*")
elif pool < 0:
    print("***")
else:
    print("****")

```

This code uses the if, elif, and else keywords to create a conditional statement that checks the value of the variable pool. Depending on whether the value is greater than, less than, or equal to zero, the code will print a different pattern of asterisks to the screen. The print function is used to display the output. The code is indented to show the blocks of code that belong to each condition. The code

will output * if the value of pool is positive, ** if the value of pool is negative, and *** if the value of pool is zero.
 You can find more information about the conditional statements and the print function in Python in the following references:
 * [Python If... Else]
 * [Python Print Function]
 * [Python Basic Syntax]

NEW QUESTION # 30

Assuming that the following assignment has been successfully executed:

```
the_list = '1', 1, 1, 1
```

Which of the following expressions evaluate to True? (Select two expressions.)

- A. the_list.index {'1'} -- 0
- B. the_List.index {"1"} in the_list
- C. len (the list [0:2]) < 3
- D. 1.1 in the_list | 1:3 |

Answer: A,C

Explanation:

The code snippet that you have sent is assigning a list of four values to a variable called "the_list". The code is as follows:

```
the_list = ['1', 1, 1, 1]
```

The code creates a list object that contains the values '1', 1, 1, and 1, and assigns it to the variable "the_list".

The list can be accessed by using the variable name or by using the index of the values. The index starts from 0 for the first value and goes up to the length of the list minus one for the last value. The index can also be negative, in which case it counts from the end of the list. For example, the_list[0] returns '1', and the_list[-1] returns 1.

The expressions that you have given are trying to evaluate some conditions on the list and return a boolean value, either True or False. Some of them are valid, and some of them are invalid and will raise an exception.

An exception is an error that occurs when the code cannot be executed properly. The expressions are as follows:

A). the_List.index {"1"} in the_list: This expression is trying to check if the index of the value '1' in the list is also a value in the list. However, this expression is invalid, because it uses curly brackets instead of parentheses to call the index method. The index method is used to return the first occurrence of a value in a list. For example, the_list.index('1') returns 0, because '1' is the first value in the list. However, the_list.index

{'1'} will raise a SyntaxError exception and output nothing.

B). 1.1 in the_list | 1:3 |: This expression is trying to check if the value 1.1 is present in a sublist of the list.

However, this expression is invalid, because it uses a vertical bar instead of a colon to specify the start and end index of the sublist. The sublist is obtained by using the slicing operation, which uses square brackets and a colon to get a part of the list. For example, the_list[1:3] returns [1, 1], which is the sublist of the list from the index 1 to the index 3, excluding the end index. However, the_list | 1:3 | will raise a SyntaxError exception and output nothing.

C). len (the list [0:2]) < 3: This expression is trying to check if the length of a sublist of the list is less than 3.

This expression is valid, because it uses the len function and the slicing operation correctly. The len function is used to return the number of values in a list or a sublist. For example, len(the_list) returns 4, because the list has four values. The slicing operation is used to get a part of the list by using square brackets and a colon. For example, the_list[0:2] returns ['1', 1], which is the sublist of the list from the index 0 to the index 2, excluding the end index. The expression len (the list [0:2]) < 3 returns True, because the length of the sublist ['1', 1] is 2, which is less than 3.

D). the_list.index {'1'} - 0: This expression is trying to check if the index of the value '1' in the list is equal to 0. This expression is valid, because it uses the index method and the equality operator correctly. The index method is used to return the first occurrence of a value in a list. For example, the_list.index('1') returns 0, because '1' is the first value in the list. The equality operator is used to compare two values and return True if they are equal, or False if they are not. For example, 0 == 0 returns True, and 0 == 1 returns False. The expression the_list.index {'1'} - 0 returns True, because the index of '1' in the list is 0, and 0 is equal to 0.

Therefore, the correct answers are C. len (the list [0:2]) < 3 and D. the_list.index {'1'} - 0.

NEW QUESTION # 31

Assuming that the phone_dir dictionary contains name:number pairs, arrange the code boxes to create a valid line of code which adds Oliver Twist's phone number (5551122333) to the directory.

Answer:

Explanation:

```
phone_dir["Oliver Twist"] = ["5551122333"]
```

Explanation:

To correctly add Oliver Twist's phone number to the phone_dir dictionary, the code must follow this phone_dir["Oliver Twist"] = ["5551122333"] Now, let's match that with your code boxes and arrange them:

```
* phone_dir
* [
* "Oliver Twist"
* ]
* =
* [
* "5551122333"
* ]
```

Final Order: phone_dir # [# "Oliver Twist" #] # = # [# "5551122333" #]

NEW QUESTION # 32

What is true about exceptions and debugging? (Select two answers.)

- A. One try-except block may contain more than one except branch.
- B. The default (anonymous) except branch cannot be the last branch in the try-except block.
- C. If some Python code is executed without errors, this proves that there are no errors in it.
- D. A tool that allows you to precisely trace program execution is called a debugger.

Answer: A,D

Explanation:

Exceptions and debugging are two important concepts in Python programming that are related to handling and preventing errors. Exceptions are errors that occur when the code cannot be executed properly, such as syntax errors, type errors, index errors, etc. Debugging is the process of finding and fixing errors in the code, using various tools and techniques. Some of the facts about exceptions and debugging are:

* A tool that allows you to precisely trace program execution is called a debugger. A debugger is a program that can run another program step by step, inspect the values of variables, set breakpoints, evaluate expressions, etc. A debugger can help you find the source and cause of an error, and test possible solutions. Python has a built-in debugger module called pdb, which can be used from the command line or within the code. There are also other third-party debuggers available for Python, such as PyCharm, Visual Studio Code, etc12

* If some Python code is executed without errors, this does not prove that there are no errors in it. It only means that the code did not encounter any exceptions that would stop the execution. However, the code may still have logical errors, which are errors that cause the code to produce incorrect or unexpected results. For example, if you write a function that is supposed to calculate the area of a circle, but you use the wrong formula, the code may run without errors, but it will give you the wrong answer. Logical errors are harder to detect and debug than syntax or runtime errors, because they do not generate any error messages. You have to test the code with different inputs and outputs, and compare them with the expected results34

* One try-except block may contain more than one except branch. A try-except block is a way of handling exceptions in Python, by using the keywords try and except. The try block contains the code that may raise an exception, and the except block contains the code that will execute if an exception occurs. You can have multiple except blocks for different types of exceptions, or for different actions to take. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except ZeroDivisionError: # handle the ZeroDivisionError exception
except: # handle any other exception
```

This way, you can customize the error handling for

different situations, and provide more informative messages or alternative solutions⁵

* The default (anonymous) except branch can be the last branch in the try-except block. The default except branch is the one that does not specify any exception type, and it will catch any exception that is not handled by the previous except branches. The default except branch can be the last branch in the try- except block, but it cannot be the first or the only branch. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except: # handle any other exception
This is a valid try-except block, and the default except branch will be the last branch. However, you cannot write a try-except block like this:
```

```
try: # some code that may raise an exception
except: # handle any exception
This is an invalid try-except block, because the default except branch is the only branch, and it will catch all exceptions, even those that are not errors, such as KeyboardInterrupt or SystemExit. This is considered a bad practice, because it may hide or ignore important exceptions that should be handled differently or propagated further. Therefore, you should always specify the exception types that you want to handle, and use the default except branch only as a last resort5 Therefore, the correct answers are A. A tool that allows you to precisely trace program execution is called a debugger. and C. One try-except block may contain more than one except branch.
```

How can I see the details of an exception in Python's debugger? Python Debugging (fixing problems) Python - start interactive debugger when exception would be otherwise thrown Python Try Except [Error Handling and Debugging - Programming with Python for Engineers]

NEW QUESTION # 33

What happens when the user runs the following code?

```
total = 0
for i in range(4):
    if 2 * i < 4:
        total += 1
    else:
        total += 2
print(total)
```

- A. The code outputs 3.
- B. The code enters an infinite loop.
- C. The code outputs 1.
- D. The code outputs 2.

Answer: D

Explanation:

The code snippet that you have sent is calculating the value of a variable "total" based on the values in the range of 0 to 3. The code is as follows:

```
total = 0
for i in range(0, 3):
    if i % 2 == 0:
        total = total + 1
    else:
        total = total + 2
print(total)
```

The code starts with assigning the value 0 to the variable "total". Then, it enters a for loop that iterates over the values 0, 1, and 2 (the range function excludes the upper bound). Inside the loop, the code checks if the current value of "i" is even or odd using the modulo operator (%). If "i" is even, the code adds 1 to the value of "total". If "i" is odd, the code adds 2 to the value of "total". The loop ends when "i" reaches 3, and the code prints the final value of "total" to the screen.

The code outputs 2 to the screen, because the value of "total" changes as follows:

- * When i = 0, total = 0 + 1 = 1
- * When i = 1, total = 1 + 2 = 3
- * When i = 2, total = 3 + 1 = 4
- * When i = 3, the loop ends and total = 4 is printed

Therefore, the correct answer is B. The code outputs 2.
