dbt Labs dbt Analytics Engineering Certification Exam Sample Questions (Q35-Q40):

NEW QUESTION # 35

You introduce a new data source for a dbt model. Production policies require review and approval of the source's schema before it can be used for reporting. How could you streamline this within your dbt project?

- A. Use dbt's ephemeral models feature to temporarily load the data for the approval process.
- B. Run a separate dbt project in production exclusively for source validation, providing access to relevant stakeholders.
- C. Create a pre-hook that automates schema validation and sends the output to the designated team.
- D. Write dbt tests that explicitly fail if the new source schema does not match the approved definition.

Answer: A,B,C

Explanation:

A provides proactive checks integrated into the workflow. B establishes a self-contained validation environment. D is an easy, controlled way for review. C is reactive and could potentially halt valid deployments.

NEW QUESTION # 36

You've made several commits to your feature branch. Before merging into the main branch, you want to consolidate the changes into a single, clear commit. What Git technique would help achieve this?

- A. Manually copy your files into a new branch, commit, and issue a pull request.
- B. Use `git rebase -i` (interactive rebase) to squash commits together.
- C. `git cherry-pick` specific commits from your branch and reapply them.
- D. Run `git rebase main` followed by `git commit -amend`.

Answer: B

Explanation:

Interactive rebasing (`git rebase -i`) provides fine-grained control to squash, edit, or rearrange commits, creating a cleaner commit history

NEW QUESTION # 37

Examine model `stg_customers_sales` that exists in the main branch:

```
select
id as customer_id,
name as customer_name
from {{ source('my_data','my_source') }}
```

A developer creates a branch `feature_a` from `main` and modifies the model as:

```
select
id as customer_id,
name as customer_name,
country as customer_country
from {{ source('my_data','my_source') }}
```

A second developer also creates a branch `feature_b` from `main` and modifies the model as:

```
select
id as customer_id,
name as customer_name,
address as customer_address
from {{ source('my_data','my_source') }}
```

The first developer creates a PR and merges `feature_a` into `main`.

Then the second developer creates a PR and attempts to merge `feature_b` into `main`.

How will git combine the code from `feature_b` and the code from `main`, which now contains the changes from `feature_a` as well?

Statement:

"As `feature_a` is already approved and merged to `main`, the code for the model `stg_customers_sales` will stay as-is and the changes

from feature_b won't be added."

- A. Yes
- B. No

Answer: B

Explanation:

Git does not automatically reject or ignore changes from the second branch (feature_b). Instead, Git attempts to merge both sets of changes, and if they modify the same lines or nearby blocks of code, Git produces a merge conflict that must be manually resolved. In this scenario, both feature_a and feature_b introduce new columns into the same SELECT statement of the same model file, meaning Git must reconcile two different edits made in parallel on branches that diverged from the same commit.

Once feature_a is merged into main, the code in main contains the new column customer_country. When developer B then tries to merge feature_b, Git compares the modified file in feature_b with the updated file in main. Since both branches changed the same section of SQL, Git cannot automatically determine the correct combined output. It will not discard feature_b's changes; instead, Git requires the developer to manually merge both sets of additions, typically resulting in a combined SELECT clause with both customer_country and customer_address, unless the developer chooses otherwise.

This behavior is documented in Git fundamentals: when multiple developers modify the same file region, manual conflict resolution is required. Therefore, the statement claiming feature_b's changes "won't be added" is incorrect.

NEW QUESTION # 38

You frequently need to implement custom SQL tests that are very similar but with slight variations in parameters. Which dbt feature could streamline this process?

- A. The relationships test
- B. dbt seeds
- C. dbt snapshots
- D. dbt macros

Answer: D

Explanation:

Macros are ideal for parameterizing reusable test logic, making it easy to adapt the tests without excessive copy-pasting.

NEW QUESTION # 39

You want to display the runtime metrics (e.g., execution time) of each model directly on the DAG node. Which challenges might you face when implementing this?

- A. Retrieving runtime metrics for each historical run might not be natively supported by dbt
- B. All of the above
- C. dbt documentation is primarily static; it might not be able to render dynamic metrics that change with each execution.
- D. Adding too much detailed information directly to the DAG could lead to visual clutter and make it overwhelming.

Answer: B

Explanation:

A: You might need to generate static summaries or find workarounds to display dynamic metrics. B: Collecting runtime metrics across all historical runs might require additional logging or integration with dbt artifacts (manifest.json, run_results.json)- C: The DAG visualization needs a balance between information and readability.
