### VMware Advanced VMware Cloud Foundation 9.0 vSphere Kubernetes Service Sample Questions (Q44-Q49):

#### NEW QUESTION # 44

A VI Administrator needs to expand the available storage options for a specific vSphere Namespace data-science. The team requires a new storage tier for temporary scratch data that does not need replication (RAID-0). The administrator has created a new VM Storage Policy named scratch-policy in vCenter that defines these non-replicated rules. What is the correct procedure to make this new policy available to the DevOps team's kubectl context within that namespace? (Select all that apply.)

- A. No action is needed; all vCenter storage policies are automatically available to all namespaces as StorageClasses.
- B. Log in to the vSphere Client, navigate to Workload Management, select the Namespace, go to the Storage card, and click Edit Storage Policies to add scratch-policy.
- C. Log in to the Supervisor Control Plane via SSH and edit the /etc/kubernetes/manifests/kube-controller-manager.yaml file to include the new policy.
- D. Instruct the DevOps team to create a StorageClass YAML with the provisioner: csi.vsphere.vmware.com and parameters.storagepolicyname: scratch-policy.
- E. Once added in the vSphere Client, verify the availability by running kubectl get storageclass within the data-science namespace context; a new class named scratch-policy should appear automatically.

**Answer: B,E**

#### NEW QUESTION # 45

A VKS Administrator needs to scale out a production Tanzu Kubernetes Grid (TKG) cluster named prod-cluster-01 to handle increased load. The goal is to increase the number of worker nodes from 3 to 5.

Review the following YAML snippet of the cluster definition:

```
apiVersion: run.tanzu.vmware.com/v1alpha3
kind: TanzuKubernetesCluster
metadata:
  name: prod-cluster-01
  namespace: production
spec:
  topology:
    controlPlane:
      replicas: 3
      vmClass: guaranteed-medium
      storageClass: gold-policy
    workers:
      replicas: 3
      vmClass: best-effort-large
      storageClass: silver-policy
```

Which specific modification to the YAML file or kubectl command will achieve the scaling requirement?

- A. Edit the YAML to set spec.topology.controlPlane.replicas: 5 and apply the change.
- B. Edit the YAML to set spec.topology.workers.replicas: 5 and apply the change using kubectl apply -f cluster.yaml.
- C. Run the command kubectl scale --replicas=5 tanzukubernetescluster/prod-cluster-01.
- D. Delete the cluster and recreate it with the new worker count.

**Answer: B**

#### NEW QUESTION # 46

In a vSphere with Tanzu architecture, how is the mapping between vSphere Storage Policies and Kubernetes StorageClasses established for the Supervisor Cluster and its Namespaces?

- A. The vSphere Administrator must manually create a StorageClass YAML definition in Kubernetes for every vSphere Storage Policy they wish to expose.
- **B. There is a one-to-one automatic mapping; assigning a vSphere Storage Policy to a vSphere Namespace automatically generates a matching Kubernetes StorageClass within that namespace.**
- C. The Supervisor Cluster uses a single default StorageClass that maps to the vSphere Datastore with the most free space; multiple policies are not supported.
- D. Storage Policies are applied directly to Virtual Machine Class definitions, not to Namespaces or StorageClasses.

**Answer: B**

#### NEW QUESTION # 47

A Cloud Administrator is troubleshooting a failed Tanzu Kubernetes Grid (TKG) cluster provisioning.

The cluster creation task in the vSphere Client indicates a failure, but the error message is generic. The administrator decides to investigate the specific controller logs on the Supervisor.

Which specific Kubernetes object events should the administrator inspect using kubectl to find the most detailed error messages regarding the infrastructure provisioning (VM cloning, networking) of the TKG cluster nodes?

- A. kubectl get events --namespace kube-system
- B. kubectl describe tanzukubernetescluster
- C. kubectl logs deployment/wcp-auth-proxy
- **D. kubectl describe virtualmachine**

**Answer: D**

#### NEW QUESTION # 48

An administrator is maintaining several Kubernetes clusters deployed through a Supervisor Namespace in a vSphere Kubernetes Service environment. One of the micro-services (a containerized API gateway) is failing intermittently after a recent configuration update. The pod is entering a CrashLoopBackOff state. The administrator needs to collect detailed runtime information directly from the pod, including both the standard output (STDOUT) and standard error (STDERR) streams, to analyze the application's behavior before the crash.

Which command produces the required output?

- A. kubectl describe
- **B. kubectl logs**
- C. kubectl get all
- D. kubectl events

**Answer: B**

Explanation:

When a container repeatedly crashes (CrashLoopBackOff), the most direct way to capture what the application emitted right before termination is to retrieve the container logs. In Kubernetes, application output written to STDOUT and STDERR is captured by the container runtime logging mechanism and exposed through the Kubernetes API for retrieval. The kubectl logs command is designed specifically for this purpose: it fetches the log stream for a pod (and container, if multiple exist), allowing administrators to review the runtime messages that typically explain configuration errors, missing dependencies, failed probes, authentication problems, or other causes of the crash loop. This aligns with VMware operational guidance that uses kubectl to retrieve pod-level operational information and logs as part of troubleshooting Kubernetes functionality running on vSphere.
