ISC Certified Information Systems Security Professional (CISSP) Sample Questions (Q1213-Q1218):

NEW QUESTION # 1213

Which type of password token involves time synchronization?

- A. Asynchronous dynamic password tokens
- B. Challenge-response tokens
- C. Static password tokens
- **D. Synchronous dynamic password tokens**

Answer: D

Explanation:

Synchronous dynamic password tokens generate a new unique password value at fixed time intervals, so the server and token need to be synchronized for the password to be accepted. NEW QUESTION # 1214

What is the term commonly used to refer to a technique of authentication one machine to another by forging packets from a trusted source?

- A. Smurfing
- B. Man-in-the-Middle (MITM) attack
- **C. Spoofing**
- D. Session redirect

Answer: C

NEW QUESTION # 1215

A web-based application known to be susceptible to attacks is now under review by a senior developer. The organization would like to ensure this application is less susceptible to injection attacks specifically, What strategy will work BEST for the organization's situation?

- A. Limit privileged access or hard-coding logon credentials,
- B. Store sensitive data in a buffer that retains data in operating system (OS) cache or memory.
- C. Do not store sensitive unencrypted data on the back end.
- **D. Whitelist input and encode or escape output before it is processed for rendering.**

Answer: D

Explanation:

Injection attacks are a type of web-based application attack that exploit the lack of proper input validation and output encoding or escaping. Injection attacks allow an attacker to inject malicious code or commands into the application, such as SQL, LDAP, OS, or HTML code, and execute them on the server or the client side. To prevent injection attacks, the best strategy is to whitelist input and encode or escape output before it is processed for rendering. Whitelisting input means that the application only accepts input that matches a predefined set of criteria, such as data type, length, format, or range, and rejects any input that does not meet these criteria. Encoding or escaping output means that the application converts any potentially dangerous characters or symbols in the output, such as <, >, &, or ', into harmless representations, such as < >, ', or &, before sending them to the browser or the database. This prevents the output from being interpreted as code or commands by the browser or the database. Not storing sensitive unencrypted data on the back end, limiting privileged access or hard-coding logon credentials, and storing sensitive data in a buffer that retains data in OS cache or memory are not effective strategies to prevent injection attacks, and may introduce other security risks. NEW QUESTION # 1216

What mechanism does a system use to compare the security labels of a subject and an object?

- A. Validation Module.

- **B. Reference Monitor.**
- C. Clearance Check.
- D. Security Module.

Answer: B

Explanation:

Because the Reference Monitor is responsible for access control to the objects by the subjects it compares the security labels of a subject and an object.

According to the OIG: The reference monitor is an access control concept referring to an abstract machine that mediates all accesses to objects by subjects based on information in an access control database. The reference monitor must mediate all access, be protected from modification, be verifiable as correct, and must always be invoked. The reference monitor, in accordance with the security policy, controls the checks that are made in the access control database.

The following are incorrect:

Validation Module. A Validation Module is typically found in application source code and is used to validate data being inputted.

Clearance Check. Is a distractor, there is no such thing other than what someone would do when checking if someone is authorized to access a secure facility.

Security Module. Is typically a general purpose module that performs a variety of security related functions.
