# CompTIA Security+ Certification Exam Sample Questions (Q500-Q505):

**NEW QUESTION # 500**
Which of the following explains why an attacker cannot easily decrypt passwords using a rainbow table attack?

- A. Perfect forward secrecy
- B. Digital signatures
- C. Salting
- D. Hashing

**Answer: C**

Explanation:
Salting is a technique used to enhance the security of hashed passwords by adding a unique, random value (salt) to each password before hashing it. This prevents attackers from easily decrypting passwords using rainbow tables, which are precomputed tables for reversing cryptographic hash functions. Since each password has a unique salt, the same password will produce different hash values, making rainbow table attacks ineffective.

**NEW QUESTION # 501**
Which of the following would be the best way to handle a critical business application that is running on a legacy server?

- A. Decommissioning
- B. Isolation
- C. Hardening
- D. Segmentation

**Answer: C**

Explanation:
A legacy server is a server that is running outdated or unsupported software or hardware, which may pose security risks and compatibility issues. A critical business application is an application that is essential for the operation and continuity of the business, such as accounting, payroll, or inventory management. A legacy server running a critical business application may be difficult to replace or upgrade, but it should not be left unsecured or exposed to potential threats.
One of the best ways to handle a legacy server running a critical business application is to harden it.
Hardening is the process of applying security measures and configurations to a system to reduce its attack surface and vulnerability.
Hardening a legacy server may involve steps such as:
* Applying patches and updates to the operating system and the application, if available
* Removing or disabling unnecessary services, features, or accounts
* Configuring firewall rules and network access control lists to restrict inbound and outbound traffic
* Enabling encryption and authentication for data transmission and storage
* Implementing logging and monitoring tools to detect and respond to anomalous or malicious activity
* Performing regular backups and testing of the system and the application Hardening a legacy server can help protect the critical business application from unauthorized access, modification, or disruption, while maintaining its functionality and availability.
However, hardening a legacy server is not a permanent solution, and it may not be sufficient to address all the security issues and challenges posed by the outdated or unsupported system. Therefore, it is advisable to plan for the eventual decommissioning or migration of the legacy server to a more secure and modern platform, as soon as possible.

**NEW QUESTION # 502**

Which of the following can best protect against an employee inadvertently installing malware on a company system?

- A. System isolation
- B. Least privilege
- C. Application allow list
- D. Host-based firewall

**Answer: B**

Explanation:

The principle of least privilege ensures that users are granted only the minimum level of access necessary to perform their job responsibilities. By implementing least privilege, employees have restricted access rights and permissions, limiting their ability to install or execute unauthorized software, including malware.

**NEW QUESTION # 503**

A new vulnerability enables a type of malware that allows the unauthorized movement of data from a system. Which of the following would detect this behavior?

- A. Monitoring outbound traffic
- B. Closing all open ports
- C. Implementing encryption
- D. Using default settings

**Answer: A**

Explanation:

Monitoring outbound traffic is essential for detecting unauthorized data exfiltration from a system. A new vulnerability that allows malware to move data unauthorizedly would typically attempt to send this data out of the network. By monitoring outbound traffic, security tools can detect unusual data transfers, trigger alerts, and help prevent the exfiltration of sensitive information.

- A. Geographic dispersion
- B. Hot site
- C. Platform diversity
- D. Load balancing

**Answer: A**

Explanation:

Geographic dispersion is the practice of having backup data stored in different locations that are far enough apart to minimize the risk of a single natural disaster affecting both sites. This ensures that the company can recover its regulated data in case of a disaster at the primary site. Platform diversity, hot site, and load balancing are not directly related to the protection of backup data from natural disasters.
