Amazon AWS Certified Developer - Associate Sample Questions (Q512-Q517):

NEW QUESTION # 512

A company's application has an AWS Lambda function that processes messages from IoT devices. The company wants to monitor the Lambda function to ensure that the Lambda function is meeting its required service level agreement (SLA).

A developer must implement a solution to determine the application's throughput in near real time. The throughput must be based on the number of messages that the Lambda function receives and processes in a given time period. The Lambda function performs initialization and post-processing steps that must not factor into the throughput measurement.

What should the developer do to meet these requirements?

- A. Modify the application to publish custom Amazon CloudWatch metrics when the Lambda function receives and processes each message. Use the metrics to calculate the throughput.
- B. Modify the application to log the calculated throughput to Amazon CloudWatch Logs. Use Amazon EventBridge to invoke a separate Lambda function to process the logs on a schedule.
- C. Use the Lambda function's Invocations metric and Duration metric to calculate the throughput in Amazon CloudWatch.
- D. Use the Lambda function's ConcurrentExecutions metric in Amazon CloudWatch to measure the throughput.

Answer: A

NEW QUESTION # 513

A company is building an application for stock trading. The application needs sub-millisecond latency for processing trade requests. The company uses Amazon DynamoDB to store all the trading data that is used to process each trading request.

A development team performs load testing on the application and finds that the data retrieval time is higher than expected. The development team needs a solution that reduces the data retrieval time with the least possible effort.

Which solution meets these requirements?

- A. Use DynamoDB Accelerator (DAX) to cache the trading data.
- B. Add retries with exponential backoff for DynamoDB queries.
- C. Store the trading data in Amazon S3, and use S3 Transfer Acceleration.
- D. Add local secondary indexes (LSIs) for the trading data.

Answer: A

NEW QUESTION # 514

A company has built an AWS Lambda function to convert large image files into output files that can be used in a third-party viewer application. The company recently added a new module to the function to improve the output of the generated files. However, the new module has increased the bundle size and has increased the time that is needed to deploy changes to the function code.

How can a developer increase the speed of the Lambda function deployment?

- A. Use Lambda layers to package and load dependencies.
- B. Increase the memory size of the function.
- C. Use Amazon S3 to host the function dependencies.
- D. Use AWS CodeDeploy to deploy the function code.

Answer: C

NEW QUESTION # 515

A developer is building an application that stores sensitive user data. The application includes an Amazon CloudFront distribution and multiple AWS Lambda functions that handle user requests.

User requests contain more than 20 data fields. Each application transaction includes sensitive data that must be encrypted. Only

specific parts of the application must be able to decrypt the data.
Which solution will meet these requirements?

- A. Configure CloudFront to require HTTPS and require users to access content by using signed URLs or signed cookies.
- B. Integrate AWS WAF with CloudFront and use a Lambda function with self-managed keys to encrypt and decrypt the data.
- **C. Configure the CloudFront distribution to use field-level encryption. Create an asymmetric AWS KMS key and configure CloudFront to use the key.**
- D. Associate the CloudFront distribution with a Lambda@Edge function. Configure the function to perform field-level asymmetric encryption by using a user-defined RSA public key stored in AWS KMS.

Answer: C

Explanation:

Amazon CloudFront field-level encryption is specifically designed to protect sensitive fields in HTTP requests. It allows CloudFront to encrypt specific request fields at the edge using asymmetric encryption, ensuring that only authorized application components that possess the private key can decrypt the data.

This approach ensures that sensitive fields remain encrypted throughout transit and processing, while non-sensitive fields can still be accessed normally. This satisfies the requirement that only specific parts of the application can decrypt the data.

Field-level encryption is a native CloudFront capability and is far more secure and scalable than implementing custom encryption logic in Lambda@Edge or Lambda functions. AWS documentation emphasizes using built-in CloudFront security features to minimize operational overhead and reduce the risk of cryptographic implementation errors.

Options A and B introduce unnecessary complexity and custom cryptographic handling, which AWS generally discourages when managed services are available. Option D only secures transport and access control and does not encrypt individual data fields. Therefore, CloudFront field-level encryption with asymmetric keys is the AWS-recommended and correct solution.

NEW QUESTION # 516

A company has an application that uses an Amazon S3 bucket for object storage. A developer needs to configure in-transit encryption for the S3 bucket. All the S3 objects containing personal data needs to be encrypted at rest with AWS Key Management Service (AWS KMS) keys, which can be rotated on demand.

Which combination of steps will meet these requirements? (Choose two.)

- A. Configure S3 Block Public Access settings for the S3 bucket to allow only encrypted connections over HTTPS.
- **B. Write an S3 bucket policy to allow only encrypted connections over HTTPS by using the aws:SecureTransport condition.**
- C. Configure an S3 bucket policy to enable client-side encryption for the objects containing personal data by using an AWS KMS customer managed key.
- D. Write an S3 bucket policy to allow only encrypted connections over HTTPS by using permissions boundary.
- **E. Configure the application to encrypt the objects by using an AWS KMS customer managed key before uploading the objects containing personal data to Amazon S3.**

Answer: B,E
