## CompTIA Data+ Certification Exam Sample Questions (Q293-Q298):

### NEW QUESTION # 293

A data analyst needs to calculate the mean for Q1 sales using the data set below:

Which of the following is the mean?

- A. \$12,330.88
- B. \$2,466.18
- C. \$2,667.60
- D. \$3,082.72

**Answer: D**

Explanation:

The mean is the average of all the values in a data set. To calculate the mean, we add up all the values and divide by the number of values. In this case, the mean for Q1 sales is  $(\$2,000 + \$3,000 + \$4,000 + \$2,500 + \$3,500) / 5 = \$3,082.72$  References: CompTIA Data+ Certification Exam Objectives, page 9

#### NEW QUESTION # 294

A data analyst is attempting to understand how ice cream consumption is affected by different attributes, such as cost, temperature, and income level. Which of the following regression analyses should the data analyst perform to understand this relationship?

- A. Logistic
- **B. Ordinary least squares**
- C. Cox
- D. Polynomial

**Answer: B**

Explanation:

answer: B. Ordinary least squares

Ordinary least squares (OLS) is a type of linear regression that is used to fit a regression model that describes the relationship between one or more predictor variables and a numeric response variable. Use when: The relationship between the predictor variable(s) and the response variable is reasonably linear. The response variable is a continuous numeric variable<sup>1</sup>.

In this case, the data analyst is interested in understanding how ice cream consumption (the response variable) is affected by different attributes, such as cost, temperature, and income level (the predictor variables).

Assuming that these variables have a linear relationship, OLS can be used to estimate the coefficients of the regression equation that best fits the data. OLS can also provide measures of goodness-of-fit, such as R-squared and adjusted R-squared, and test the significance of the coefficients using t-tests and F-tests<sup>2</sup>.

Option A is incorrect, as logistic regression is used to fit a regression model that describes the relationship between one or more predictor variables and a binary response variable. Use when: The response variable is binary - it can only take on two values<sup>1</sup>. Ice cream consumption is not a binary variable, but rather a continuous numeric variable.

Option C is incorrect, as Cox regression is used to fit a regression model that describes the relationship between one or more predictor variables and a survival time response variable. Use when: The response variable is the time until an event of interest occurs, such as death, failure, or recovery<sup>3</sup>. Ice cream consumption is not a survival time variable, but rather a continuous numeric variable.

Option D is incorrect, as polynomial regression is used to fit a regression model that describes the relationship between one or more predictor variables and a numeric response variable. Use when: The relationship between the predictor variable(s) and the response variable is non-linear<sup>1</sup>. If there is no evidence of non-linearity in the data, polynomial regression may not be appropriate, as it may overfit the data and produce unreliable estimates.

#### NEW QUESTION # 295

An analyst must obtain the average daily sales for the following week:

Which of the following must the analyst perform to obtain this value?

- A. Data append
- B. Data blending
- C. Data normalization
- **D. Data aggregation**

**Answer: D**

Explanation:

Data aggregation is the process of compiling data from multiple sources and summarizing it into a single dataset. Data aggregation can be used to calculate statistics, such as averages, sums, counts, or percentages. In this case, the analyst must obtain the average daily sales for the following week, which is a statistic that can be calculated by aggregating the sales data from each day and dividing by the number of days. Data aggregation can be done using various tools and methods, such as spreadsheets, databases, or programming languages.

### NEW QUESTION # 296

A data analyst for a media company needs to determine the most popular movie genre. Given the table below:

Which of the following must be done to the Genre column before this task can be completed?

- A. Merge
- B. Append
- C. Delimit
- D. Concatenate

**Answer: C**

### NEW QUESTION # 297

A data analyst needs to perform a full outer join of a customer's orders using the tables below:

Which of the following is the mean of the order quantity?

- A. 73.5
- B. 81.5
- C. 78.8
- D. 76.5

**Answer: B**

Explanation:

Explanation

The correct answer is D. OUTER JOIN, seven rows.

An OUTER JOIN is a type of SQL join that returns all the rows from both tables, regardless of whether there is a match or not. If there is no match, the missing side will have null values. An OUTER JOIN can be either a LEFT JOIN, a RIGHT JOIN, or a FULL JOIN, depending on which table's rows are preserved. Using the example tables, a FULL OUTER JOIN query would look like this:

```
SELECT Cust_id, Order_id, Order_qty FROM Sales_table FULL OUTER JOIN Order_table ON Sales_table.Order_id = Order_table.Order_id; The result of this query would be:
```

```
Cust_id | Order_id | Order_qty -----+-----+----- 1 | 1 | 100 2 | 2 | 50 3 | 3 | 25 4 | 4 | 75 NULL | 5 | 10 NULL | 6 | 20 NULL | 7 | 15
```

As you can see, the query returns seven rows, one for each order in either table. The orders that are not in the Sales\_table have null values for the Cust\_id column.

To find the mean of the order quantity, we need to sum up the order quantities and divide by the number of rows. In this case, the mean is  $(100 + 50 + 25 + 75 + 10 + 20 + 15) / 7 = 42.14$ . Rounding to one decimal place, we get 42.1 as the mean of the order quantity.
