Amazon AWS Certified DevOps Engineer - Professional Sample Questions (Q553-Q558):

NEW QUESTION # 553

An Application team has three environments for their application: development, pre-production, and production. The team recently adopted AWS CodePipeline.

However, the team has had several deployments of misconfigured or nonfunctional development code into the production environment, resulting in user disruption and downtime. The DevOps Engineer must review the pipeline and add steps to identify problems with the application before it is deployed.

What should the Engineer do to identify functional issues during the deployment process? (Choose two.)

- A. Create an AWS CodeDeploy action in the pipeline with a deployment configuration that automatically deploys the application code to a limited number of instances. The action then pauses the deployment so that the QA team can review the application functionality. When the review is complete, CodeDeploy resumes and deploys the application to the remaining production Amazon EC2 instances.
- B. Using AWS CodeBuild to add a test action to the pipeline to replicate common user activities and ensure that the results are as expected before progressing to production deployment.
- C. Add an AWS CodeDeploy action in the pipeline to deploy the latest version of the development code to pre-production. Add a manual approval action in the pipeline so that the QA team can test and confirm the expected functionality. After the manual approval action, add a second CodeDeploy action that deploys the approved code to the production environment.
- D. After the deployment process is complete, run a testing activity on an Amazon EC2 instance in a different region that accesses the application to simulate user behavior. If unexpected results occur, the testing activity sends a warning to an Amazon SNS topic. Subscribe to the topic to get updates.
- E. Use Amazon Inspector to add a test action to the pipeline. Use the Amazon Inspector Runtime Behavior Analysis Inspector rules package to check that the deployed code complies with company security standards before deploying it to production.

Answer: A,E

- If the application fails, an automated healing mechanism will replace the affected instances.

Which deployment strategy will meet these requirements?

- A. Use AWS CodeDeploy with Auto Scaling and an Elastic Load Balancer.
Use a blue/green deployment strategy.
Enable an Elastic Load Balancing health check to report the status of the application, and set the Auto Scaling health check to ELB.
- B. Create an AWS Elastic Beanstalk environment and configure it to use Auto Scaling and an Elastic Load Balancer.
Use rolling deployments with a batch size of 50%.
- C. Use AWS CodeDeploy with Auto Scaling and an Elastic Load Balancer.

NEW QUESTION # 555

You need to grant a vendor access to your AWS account. They need to be able to read protected messages in a private S3 bucket at their leisure. They also use AWS. What is the best way to accomplish this?

- A. Create a cross-account IAM Role with permission to access the bucket, and grant permission to use the Role to the vendor AWS account.
D- Generate a signed S3 PUT URL and a signed S3 GET URL, both with wildcard values and 2 year durations. Pass the URLs to the vendor.
- B. Create an EC2 Instance Profile on your account. Grant the associated IAM role full access to the bucket.
Start an EC2 instance with this Profile and give SSH access to the instance to the vendor.
- C. Create an IAM User with API Access Keys. Grant the User permissions to access the bucket. Give the vendor the AWS Access Key ID and AWS Secret Access Key for the User.

Answer: A

Explanation:

Explanation

You can use AWS Identity and Access Management (IAM) roles and AWS Security Token Service (STS) to set up cross-account access between AWS accounts. When you assume an IAM role in another AWS account to obtain cross-account access to services and resources in that account, AWS CloudTrail logs the cross-account activity. NEW QUESTION # 556

A company recently migrated its legacy application from on-premises to AWS. The application is hosted on Amazon EC2 instances behind an Application Load Balancer, which is behind Amazon API Gateway. The company wants to ensure users experience minimal disruptions during any deployment of a new version of the application. The company also wants to ensure it can quickly roll back updates if there is an issue.

Which solution will meet these requirements with MINIMAL changes to the application?

- A. Introduce changes as a separate target group behind the existing Application Load Balancer. Configure API Gateway to route all traffic to the Application Load Balancer, which then sends the traffic to the new target group.
- **B. Introduce changes as a separate environment parallel to the existing one. Configure API Gateway to use a canary release deployment to send a small subset of user traffic to the new environment.**
- C. Introduce changes as a separate environment parallel to the existing one. Update the application's DNS alias records to point to the new environment.
- D. Introduce changes as a separate target group behind the existing Application Load Balancer. Configure API Gateway to route user traffic to the new target group in steps.

Answer: B

NEW QUESTION # 557

A company's web application will be migrated to AWS. The application is designed so that there is no server-side code required. As part of the migration, the company would like to improve the security of the application by adding HTTP response headers, following the Open Web Application Security Project (OWASP) secure headers recommendations.

How can this solution be implemented to meet the security requirements using best practices?

- A. Use an Amazon S3 bucket configured for website hosting, then set up server access logging on the S3 bucket to track user activity. Configure the static website hosting to return the required security headers.
- B. Use an Amazon S3 bucket configured for website hosting. Create an Amazon CloudFront distribution that refers to this S3 bucket, with the origin response event set to trigger a Lambda@Edge Node.js function to add in the security headers.
- C. Use an Amazon S3 bucket configured for website hosting, then set up server access logging on the S3 bucket to track user activity. Then configure the static website hosting and execute a scheduled AWS Lambda function to verify, and if missing, add security headers to the metadata.
- **D. Set an Amazon S3 bucket configured for website hosting. Create an Amazon CloudFront distribution that refers to this S3 bucket. Set "Cache Based on Selected Request Headers" to "Whitelist," and add the security headers into the whitelist.**

Answer: D
