`}`  
`}`  
`}`

**Answer: E**

Explanation:

The "optimal" Apex trigger logic is defined by its bulkification and strict adherence to Salesforce governor limits. In Apex, a trigger can process up to 200 records in a single batch. If a developer places a SOQL query inside a loop, the transaction will fail with a `System.LimitException` if more than 100 records are processed, as the limit is 100 synchronous SOQL queries.

Option A follows the industry-standard "Bulkify, Query, and Map" design pattern:

\* Collection: It iterates through the input records once to gather all relevant search criteria (Zip Codes) into a Set.

\* External Query: It performs a single SOQL query outside of any loop to fetch all matching `Region__c` records for the entire batch. This is the most critical step for scalability.

\* Mapping: It organizes the results into a `Map<String, String>` (Zip Code to Region Name). Maps provide  $O(1)$  constant-time lookup performance.

\* Final Assignment: It iterates through the Leads a second time and assigns the Region using the Map.

Options B, C, and D are all anti-patterns. Option C is the most dangerous, as it executes a query for every single record. Options B and D are slightly better but still redundant, as they execute a query inside a loop that retrieves data already retrieved in previous iterations. Only Option A ensures the code is efficient, bulk-safe, and stays well within governor limits even under heavy data loads.
