Our 3V0-24.25 study materials include 3 versions and they are the PDF version, PC version, APP online version. You can understand each version's merits and using method in detail before you decide to buy our 3V0-24.25 learning guide. And the content of the three different versions is the same, but the displays are totally different according to the study interest and hobbies. And it is quite enjoyable to learn with our 3V0-24.25 Exam Questions.

VMware Advanced VMware Cloud Foundation 9.0 vSphere Kubernetes Service Sample Questions (Q87-Q92):

NEW QUESTION # 87

A Cloud Administrator is troubleshooting a "Configuring" hang during the enabling of Workload Management on a cluster using the NSX Advanced Load Balancer (Avi) with VDS networking.

The Supervisor Control Plane VMs have powered on, but the process does not advance. The administrator checks the Avi Controller dashboard and notices that no Virtual Services (VS) have been created for the Supervisor VIP.

Review the following log snippet from the Supervisor's wepsvc.log:

```
E1125 14:00:05.123 [avi_controller_client] Failed to authenticate to Avi Controller '192.168.20.10':
```

```
401 Unauthorized. Invalid credentials.
```

What is the corrective action? (Choose 2.)

- A. Verify that the username and password specified for the Avi Controller in the Workload Management wizard are correct and have not expired.
- B. Update the credentials in the Supervisor configuration via the vSphere Client.
- C. Restart the Avi Service Engines.
- D. Ensure the Avi Controller certificate provided during setup matches the current certificate on the Avi Controller (check for thumbprint mismatch).
- E. Re-deploy the Supervisor Control Plane VMs.

Answer: A,B

NEW QUESTION # 88

What is the purpose of the VMware vSphere Kubernetes Service (VKS) Service Mesh?

- A. Provides an infrastructure layer that makes communication between applications possible, structured, and observable.
- B. Provides a centralized, global routing table to simplify and optimize traffic management.
- C. Provides dynamic application load balancing and autoscaling across multiple clusters and multiple sites.
- D. Provides service discovery across multiple clusters.

Answer: A

Explanation:

A service mesh is an application communication layer that standardizes service-to-service traffic inside Kubernetes. Instead of each development team building custom logic for retries, timeouts, encryption, and telemetry, the mesh provides these capabilities consistently across workloads. This is typically done by inserting a data plane (often sidecar proxies or node-level proxies) that intercepts inbound and outbound traffic for each microservice, plus a control plane that distributes configuration and identity material. The key outcomes align directly to option B: communication becomes possible (reliable connectivity patterns), structured (consistent routing rules, policies, and identity), and observable (metrics, logs, and distributed tracing for east-west traffic). A service mesh commonly adds controls such as mTLS encryption, fine-grained traffic policy (allow/deny, rate limits, circuit breaking), and progressive delivery patterns (canary/blue-green) without changing application code.

By contrast, service discovery (A) is usually a built-in Kubernetes function, load balancing/autoscaling across sites (C) is not the primary definition of a service mesh, and a single centralized global routing table (D) is not how meshes are typically described or implemented.

NEW QUESTION # 89

A Platform Engineer needs to configure a vSphere Namespace to allow a specific Active Directory group, dev-admins@corp.local, to have full administrative access to the Kubernetes namespace, including the ability to create and delete TKG clusters. The solution must follow the principle of least privilege within vSphere.

Which configuration steps in the vSphere Client will achieve this? (Select all that apply.)

- A. Assign the Administrator role to dev-admins@corp.local at the vCenter Server Global Permissions level.
- B. In the Namespace permissions, add dev-admins@corp.local with the CanEdit role.
- C. Ensure the Identity Source corp.local is configured in vCenter Single Sign-On.
- D. In the Namespace permissions, add dev-admins@corp.local with the Owner role.
- E. Assign the NSX Administrator role to dev-admins@corp.local in NSX Manager.

Answer: C,D

NEW QUESTION # 90

An administrator is adding a kubernetes cluster to an existing namespace. Click where the administrator navigates to create the cluster.

Answer:

Explanation:

Explanation:

Kubernetes Service

When adding a Kubernetes cluster to an existing vSphere Namespace, the workflow is initiated from within that namespace's context in the vSphere Client. The administrator first opens the target namespace (as shown in the left navigation where the namespace is selected), then uses the Kubernetes Service area to create and manage Kubernetes clusters associated with that namespace. In the namespace Summary view, the Kubernetes Service tile/card provides the entry point for cluster lifecycle actions, typically via an action link such as Manage (and from there Create Cluster). This is because the Kubernetes cluster is a namespace-scoped resource in the Supervisor environment: it inherits namespace-level policies and configuration such as permissions/RBAC, resource limits, storage policies, and networking selections that have already been defined for that namespace. Navigating to other areas like Storage or Network is used to validate or adjust prerequisites (for example, storage policy availability or network settings), but the actual "create cluster" operation is launched from Kubernetes Service within the namespace to ensure the cluster is created under the correct tenant boundary and governance model.

NEW QUESTION # 91

A Platform Engineer attempts to create a snapshot of a PVC named mysql-data but the VolumeSnapshot object remains in a ReadyToUse: False state.

The engineer inspects the status:

```
$ kubectl describe volumesnapshot mysql-snap
```

...

Status:

Ready To Use: false

Error: Snapshot creation failed: Error: CNS: CnsVolumeNotFound

What is the most likely cause of this error? (Choose 2.)

- A. The PVC mysql-data is currently mounted by a running Pod, and the vSphere CSI driver (in certain versions/configurations) or the specific filesystem requires the volume to be quiesced or unmounted (or the FCD ID is missing/mismatched).
- B. The Namespace quota for snapshots has been exceeded.
- C. The virtual disk (VMDK) associated with the PV was manually moved to a different datastore using Storage vMotion without updating the CNS metadata.
- D. The underlying Persistent Volume (PV) backing the PVC mysql-data has been deleted or detached from the CNS (Cloud Native Storage) perspective in vSphere.
- E. The VolumeSnapshotClass specified does not exist.

Answer: C,D
