ISC Certified Information Systems Security Professional (CISSP) Sample Questions (Q1516-Q1521):

NEW QUESTION # 1516

An organization has decided to contract with a cloud-based service provider to leverage their identity as a service offering. They will use Open Authentication (OAuth) 2.0 to authenticate external users to the organization's services.

As part of the authentication process, which of the following must the end user provide?

- A. A password
- B. A username and password
- C. A username
- **D. An access token**

Answer: D

NEW QUESTION # 1517

Which of the following statements is TRUE about Secure Shell (SSH)?

- **A. SSH supports port forwarding, which can be used to protect less secured protocols.**
- B. SSH is easy to deploy because it requires a Web browser only.
- C. SSH does not protect against man-in-the-middle (MITM) attacks.
- D. SSH can be used with almost any application because it is concerned with maintaining a circuit.

Answer: A

Explanation:

The true statement about Secure Shell (SSH) is that SSH supports port forwarding, which can be used to protect less secured protocols. SSH is a protocol that provides secure and encrypted communication and connection between two systems or devices over an unsecured or public network, such as the internet. SSH supports port forwarding, which is a technique that allows the user to redirect or tunnel the network traffic from one port or system to another port or system, through the SSH connection. Port forwarding can be used to protect less secured protocols, such as Telnet, FTP, or HTTP, by encrypting and securing the network traffic that uses those protocols, and preventing any interception, modification, or eavesdropping of the data or the information. The other statements are not true about SSH. SSH does protect against man-in-the-middle (MITM) attacks, which are attacks where an attacker intercepts, modifies, or relays the communication or the connection between two systems or devices, without their knowledge or consent. SSH protects against MITM attacks by using public key cryptography and digital signatures, which ensure the identity and the authenticity of the systems or devices, and prevent any tampering or spoofing of the data or the information. SSH cannot be used with almost any application, because it is not concerned with maintaining a circuit, but rather with establishing a session. A circuit is a physical or logical path or connection between two systems or devices, and it can be used by various applications or protocols, such as TCP or UDP. A session is a logical or virtual connection between two systems or devices, and it is used by a specific application or protocol, such as SSH or Telnet. SSH is not easy to deploy, because it does not require a web browser only, but rather a client and a server software, and a pair of public and private keys. A web browser is a software application that allows the user to access and view the web pages or the websites on the internet, and it uses the HTTP or HTTPS protocol, not the SSH protocol. A client is a software application that allows the user to initiate and request the SSH connection to another system or device. A server is a software application that allows the system or device to accept and respond to the SSH connection from another system or device. A public key is a cryptographic key that is shared or distributed to the other systems or devices, and it is used to encrypt or verify the data or the information. A private key is a cryptographic key that is kept secret or private by the system or device, and it is used to decrypt or sign the data or the information.
