### 問題 #12

Consider a scenario where you need to create a custom function (UDF) in Snowflake that uses an external Python library not available in the Snowflake Anaconda channel. How would you package and deploy this UDF, ensuring proper dependency management and version control?

- A. Create a Python virtual environment, install the necessary libraries, and upload the entire environment as a ZIP file to a Snowflake stage. Then, create the UDF referencing the uploaded ZIP file.
- B. Package the UDF code and the external library as a single Python file, upload it to a Snowflake stage, and then create the UDF referencing the uploaded file.
- C. Copy the source code of the external Python library and include it directly within the UDF definition. Snowflake will automatically resolve the dependencies.
- **D. Use the 'snowflake-snowpark-python' library to create a Snowpark session, package the UDF and its dependencies using Conda, and deploy the resulting environment to a Snowflake stage, referencing it in the UDF definition.**
- E. Install the required Python libraries directly on the Snowflake compute nodes using a startup script, and then create the UDF referencing the installed libraries.

答案： D

解題說明：

Option D describes the recommended approach using Snowpark and Conda. This allows for proper dependency management and version control by packaging the UDF and its dependencies into a Conda environment. Options A and C lack proper dependency management.

Option B is not feasible as you cannot directly install packages on Snowflake compute nodes.

Option E is impractical and violates code organization principles.

### 問題 #13

How can users integrate Streamlit with Snowflake notebooks?

- A. By creating manual scripts
- B. By configuring network settings
- C. By using Streamlit functions within Python code in the notebook
- D. By writing HTML code

答案： C

解題說明：

Snowflake Notebooks provide native integration with Streamlit, allowing users to build interactive data apps directly inside Snowflake. Users can call Streamlit functions such as `st.write()`, `st.dataframe()`, `st.button()`, and `st.slider()` within Python cells. No external HTML, scripting, or network configuration is required. Streamlit components execute seamlessly in the notebook environment, enabling dashboards and interactive visualizations on top of Snowflake data.

### 問題 #14

What is a key feature of Snowflake notebooks?

- A. Text-only data display
- B. Integrated environment for writing queries and visualizing results
- C. Manual hardware configuration
- D. Command-line interface only

答案： B

解題說明：

Snowflake Notebooks provide an integrated, interactive development environment that enables users to write SQL and Python code, visualize results, and document analysis—all in the same workspace. They support data visualizations, charts, tables, and Streamlit-based interactions. Notebooks run entirely within Snowsight and require no manual hardware configuration. They are not CLI-based and support much richer displays than plain text. This integration streamlines the entire data exploration, transformation, and modeling workflow.

### 問題 #15

A data engineering team uses Snowflake to load and transform large datasets. They have observed that a specific transformation job consistently takes an unacceptably long time to complete, even though the warehouse is sized at X-LARGE. Which of the following actions, individually or in combination, would be MOST effective in reducing the job's execution time?

- A. Enable Multi-cluster warehouse and set the minimum and maximum clusters to 1 and 1 respectively. This will allow for automatic scaling.
- B. Partition the source data into smaller files. Smaller files are always loaded faster.
- C. Upgrade the warehouse to a 2X-LARGE size. This ensures more compute resources are available.
- D. Review the query execution plan to identify performance bottlenecks such as full table scans or inefficient joins, and optimize the SQL code accordingly. This is often more effective than simply increasing warehouse size.
- E. Change the warehouse from 'Auto-Suspend' to 'Never-suspend' to keep the warehouse active even when idle.

答案： D

解題說明：

While increasing warehouse size (A) might help, it's a brute-force approach. Multi-cluster with min/max set to 1 (B) is essentially a single warehouse. 'Never-suspend' (D) only keeps the warehouse running, not faster. Smaller files (E) is relevant during data loading but the question focuses on transformation. The most effective action is always optimizing the SQL query itself (C). This addresses the root cause of the performance issue, which is likely inefficient query processing, rather than simply throwing more hardware at the problem. Analyzing the query plan will reveal bottlenecks that can be addressed with indexing, query rewriting, or data clustering.

#### 問題 #16

Where do tables reside in Snowflake?

- A. Virtual warehouses
- B. File formats
- C. Schemas
- D. Stages

答案： C

解題說明：

In Snowflake's logical hierarchy, tables reside within schemas, and schemas reside within databases. This structured arrangement allows clear organization, access management, and separation of workloads or business domains. A schema functions as a container that holds tables, views, functions, sequences, stages, and file formats. When users reference a table, they typically qualify it using the full three-part name:

database.schema.table.

Stages are used to store or reference files, not to hold structured database tables. Virtual warehouses provide compute power for executing queries and performing DML operations but do not store data. File formats define how staged files should be interpreted (CSV, JSON, Parquet, etc.) and are unrelated to where tables physically reside.

Snowflake separates compute and storage, so while compute happens in virtual warehouses, all persistent data-including tables-is managed in Snowflake's centralized storage layer, organized through schemas and databases. This organization ensures consistency, ease of management, and predictable access control.
