## Amazon AWS Certified Developer Associate Exam (DVA-C02) Sample Questions (Q57-Q62):

### NEW QUESTION # 57

A company has a two-tier application running on an Amazon EC2 server that handles all of its AWS based e-commerce activity. During peak times, the backend servers that process orders are overloaded with requests.

This results in some orders failing to process. A developer needs to create a solution that will re-factor the application. Which steps will allow for more flexibility during peak times, while still remaining cost-effective? (Select TWO.)

- A. Use an Amazon SNS queue to decouple the front-end and backend servers.
- B. Increase the backend T2 EC2 instance size to xl to handle the largest possible load throughout the year
- C. Migrate the backend servers to on-premises and pull from an Amazon SNS queue
- D. implement an Amazon SQS queue to decouple the front-end and backend servers
- E. Modify the backend servers to pull from an Amazon SQS queue.

**Answer: A,C**

#### NEW QUESTION # 58

A developer has created an AWS Lambda function that makes queries to an Amazon Aurora MySQL DB instance. When the developer performs a test the DB instance shows an error for too many connections.

Which solution will meet these requirements with the LEAST operational effort?

- A. Configure the Amazon Aurora MySQL DB instance for Multi-AZ deployment.
- **B. Create a proxy in Amazon RDS Proxy Query the proxy instead of the DB instance.**
- C. Migrate the data to an Amazon DynamoDB database.
- D. Create a read replica for the DB instance Query the replica DB instance instead of the primary DB instance.

**Answer: B**

Explanation:

This solution will meet the requirements by using Amazon RDS Proxy, which is a fully managed, highly available database proxy for Amazon RDS that makes applications more scalable, more resilient to database failures, and more secure. The developer can create a proxy in Amazon RDS Proxy, which sits between the application and the DB instance and handles connection management, pooling, and routing. The developer can query the proxy instead of the DB instance, which reduces the number of open connections to the DB instance and avoids errors for too many connections. Option A is not optimal because it will create a read replica for the DB instance, which may not solve the problem of too many connections as read replicas also have connection limits and may incur additional costs. Option B is not optimal because it will migrate the data to an Amazon DynamoDB database, which may introduce additional complexity and overhead for migrating and accessing data from a different database service. Option C is not optimal because it will configure the Amazon Aurora MySQL DB instance for Multi-AZ deployment, which may improve availability and durability of the DB instance but not reduce the number of connections.

#### NEW QUESTION # 59

A developer is updating an application deployed on AWS Elastic Beanstalk. The new version is incompatible with the old version. To successfully deploy the update, a full cutover to the new updated version must be performed on all instances at one time, with the ability to roll back changes in case of a deployment failure in the new version. How can this be performed with the LEAST amount of downtime?

- A. Perform an Elastic Beanstalk Rolling deployment
- B. Perform an Elastic Beanstalk Rolling with additional batch deployment
- **C. Deploy the new version in a new Elastic Beanstalk environment and swap environment URLs**
- D. Use the Elastic Beanstalk All at once deployment policy to update all instances simultaneously

**Answer: C**

#### NEW QUESTION # 60

A Developer is storing sensitive documents in Amazon S3 that will require encryption at rest. The encryption keys must be rotated annually, at least.

What is the easiest way to achieve this?

- **A. Use AWS KMS with automatic key rotation**
- B. Encrypt the data before sending it to Amazon S3
- C. Export a key from AWS KMS to encrypt the data
- D. Import a custom key into AWS KMS with annual rotation enabled

**Answer: A**

Explanation:

Explanation

<https://docs.aws.amazon.com/kms/latest/developerguide/rotate-keys.html>

<https://docs.aws.amazon.com/kms/latest/developerguide/custom-key-store-overview.html> You can use the same techniques to view and manage the CMKs in your custom key store that you use for CMKs in the AWS KMS key store. You can control access with IAM and key policies, create tags and aliases, enable and disable the CMKs, and schedule key deletion. You can use the CMKs

for cryptographic operations and use them with AWS services that integrate with AWS KMS. However, you cannot enable automatic key rotation and you cannot import key material into a CMK in a custom key store.

Q: Can I rotate my keys? Yes. You can choose to have AWS KMS automatically rotate CMKs every year, provided that those keys were generated within AWS KMS HSMs. Automatic key rotation is not supported for imported keys, asymmetric keys, or keys generated in an AWS CloudHSM cluster using the AWS KMS custom key store feature. If you choose to import keys to AWS KMS or asymmetric keys or use a custom key store, you can manually rotate them by creating a new CMK and mapping an existing key alias from the old CMK to the new CMK. <https://aws.amazon.com/kms/faqs/>

### NEW QUESTION # 61

During non-peak hours, a Developer wants to minimize the execution time of a full Amazon DynamoDB table scan without affecting normal workloads. The workloads average half of the strongly consistent read capacity units during non-peak hours.

How would the Developer optimize this scan?

- A. Use sequential scans
- **B. Use parallel scans while limiting the rate**
- C. Increase read capacity units during the scan operation
- D. Change consistency to eventually consistent during the scan operation

**Answer: B**

Explanation:

Explanation

Parallel scans would help improve the scan performance while using limit parameter the provisioned throughput consumed can be limited.

Refer AWS documentation - DynamoDB Parallel Scan

By default, the Scan operation processes data sequentially. DynamoDB returns data to the application in 1 MB increments, and an application performs additional operations to retrieve the next 1 MB of data.

The larger the table or index being scanned, the more time it takes to complete. In addition, a sequential Scan might not always be able to fully utilize the provisioned read throughput capacity: Even though DynamoDB distributes a large table's data across multiple physical partitions, a Scan operation can only read one partition at a time. For this reason, the throughput of a Scan is constrained by the maximum throughput of a single partition.

To address these issues, the Scan operation can logically divide a table or secondary index into multiple segments, with multiple application workers scanning the segments in parallel. Each worker can be a thread (in programming languages that support multithreading) or an operating system process.

A parallel scan with a large number of workers can easily consume all of the provisioned throughput for the table or index being scanned. It is best to avoid such scans if the table or index is also incurring heavy read or write activity from other applications.

To control the amount of data returned per request, use the Limit parameter. This can help prevent situations where one worker consumes all of the provisioned throughput, at the expense of all other workers.
