Amazon AWS Certified Solutions Architect - Associate (SAA-C03) Sample Questions (Q213-Q218):

NEW QUESTION # 213

A Solutions Architect needs a storage solution for a fleet of Linux web application servers. The solution should provide file system

interface and be able to support millions of files. Which AWS service should the Architect choose?

- **A. Amazon EFS**
- B. Amazon ElastiCache
- C. Amazon EBS
- D. Amazon S3

Answer: A

NEW QUESTION # 214

Which of the following are true regarding encrypted Amazon Elastic Block Store (EBS) volumes? Choose 2 answers

- **A. Snapshots are automatically encrypted**
- **B. Supported on all Amazon EBS volume types**
- C. Available to all instance types
- D. shared volumes can be encrypted
- E. Existing volumes can be encrypted

Answer: A,B

Explanation:

This feature is supported on all Amazon EBS volume types (General Purpose (SSD), Provisioned IOPS (SSD), and Magnetic). You can access encrypted Amazon EBS volumes the same way you access existing volumes; encryption and decryption are handled transparently and they require no additional action from you, your Amazon EC2 instance, or your application. Snapshots of encrypted Amazon EBS volumes are automatically encrypted, and volumes that are created from encrypted Amazon EBS snapshots are also automatically encrypted.

NEW QUESTION # 215

A company is designing a website that displays stock market prices to users. The company wants to use Amazon ElastiCache (Redis OSS) for the data caching layer. The company needs to ensure that the website's data caching layer can automatically fail over to another node if necessary.

- A. Enable read replicas in ElastiCache (Redis OSS). Promote the read replica when necessary.
- B. Export a backup of the ElastiCache (Redis OSS) cache by using AWS Backup. Restore the cache to a second cluster when necessary.
- C. Export a backup of the ElastiCache (Redis OSS) cache to an Amazon S3 bucket. Restore the cache to a second cluster when necessary.
- **D. Enable Multi-AZ in ElastiCache (Redis OSS). Fail over to a second node when necessary.**

Answer: D

Explanation:

For high availability, Amazon ElastiCache for Redis supports Multi-AZ with automatic failover, which provides primary and replica nodes in different Availability Zones. If the primary node fails, Redis automatically promotes a replica to primary.

From AWS Documentation:

"When you enable Multi-AZ with automatic failover, Amazon ElastiCache automatically detects failures and promotes a read replica to primary with minimal downtime." (Source: Amazon ElastiCache for Redis User Guide) Why B is correct:

Multi-AZ provides automatic failover and data replication.

Ensures continuous availability and protects against node or AZ failures.

Fully managed with no manual intervention needed.

Why others are incorrect:

A: Manual promotion is not automatic.

C & D: Restoring from backup is slow and meant for disaster recovery, not failover.

NEW QUESTION # 216

A company is planning to store data on Amazon RDS DB instances. The company must encrypt the data at rest. What should a solutions architect do to meet this requirement?

- **A. Create an encryption key and store the key in AWS Secrets Manager Use the key to encrypt the DB instances**
- B. Generate a certificate in AWS Certificate Manager (ACM). Enable SSL/TLS on the DB instances by using the certificate
- C. Generate a certificate in AWS Identity and Access Management (IAM) Enable SSUTLS on the DB instances by using the certificate
- D. Create a customer master key (CMK) in AWS Key Management Service (AWS KMS) Enable encryption for the DB instances

Answer: A

Explanation:

Explanation

To encrypt data at rest in Amazon RDS, you can use the encryption feature of Amazon RDS, which uses AWS Key Management Service (AWS KMS). With this feature, Amazon RDS encrypts each database instance with a unique key. This key is stored securely by AWS KMS. You can manage your own keys or use the default AWS-managed keys. When you enable encryption for a DB instance, Amazon RDS encrypts the underlying storage, including the automated backups, read replicas, and snapshots.

NEW QUESTION # 217

A company's legacy application is currently relying on a single-instance Amazon RDS MySQL database without encryption. Due to new compliance requirements all existing and new data in this database must be encrypted. How should this be accomplished?

- A. Enable RDS Multi-AZ mode with encryption at rest enabled. Perform a failover to the standby instance to delete the original instance
- **B. Take a snapshot of the RDS instance. Create an encrypted copy of the snapshot. Restore the RDS instance from the encrypted snapshot.**
- C. Create an Amazon S3 bucket with server-side encryption enabled Move all the data to Amazon S3 Delete the RDS instance
- D. Create an RDS read replica with encryption at rest enabled Promote the read replica to master and switch the application over to the new master Delete the old RDS instance

Answer: B
