CompTIA Linux+ Certification Exam Sample Questions (Q38-Q43):

NEW QUESTION # 38

Application owners are reporting that their application stops responding after several days of running, and they need to restart it. A

Linux administrator obtains the following details from the `dmesg` command:

```
invoked oom-killer
```

```
Call Trace:
```

```
out_of_memory
```

```
oom_kill_process
```

The application owners mentioned that resources to the system have been increased, and the error takes longer to appear. Which of the following best describes the reason the process is being terminated by OOM?

- A. The kernel has panicked.
- **B. The application might have a memory leak.**
- C. The CPU type is incompatible with the application.
- D. The swap configuration is not correctly sized.

Answer: B

Explanation:

The correct answer is C. The application might have a memory leak because the `dmesg` output clearly shows that the Linux kernel is invoking the OOM (Out Of Memory) killer, which terminates processes when the system runs out of available memory. The presence of entries such as `invoked oom-killer`, `out_of_memory`, and `oom_kill_process` confirms that the system is exhausting its memory resources over time.

A key detail in the scenario is that the application runs for several days before failing, and when system resources (RAM) are increased, the issue takes longer to occur. This behavior is a classic indicator of a memory leak, where an application gradually consumes more memory without releasing it. Instead of stabilizing, memory usage continuously grows until it reaches the system limit, at which point the OOM killer terminates the process to prevent system instability.

Option A (CPU type is incompatible) is incorrect because CPU incompatibility would cause immediate execution failures, not delayed memory exhaustion. Option B (kernel panic) is incorrect because a kernel panic would crash the entire system, not selectively terminate a user-space process. Option D (swap configuration not correctly sized) is partially plausible but not the best answer; while insufficient swap can contribute to OOM conditions, it does not explain the gradual memory consumption pattern observed.

In Linux+ troubleshooting, identifying memory leaks is critical when dealing with long-running applications.

Administrators should monitor memory usage using tools like `top`, `htop`, or `ps`, and investigate application behavior. Applying patches, optimizing code, or restarting services periodically are common mitigation strategies, along with configuring appropriate memory and swap resources.

NEW QUESTION # 39

Which of the following commands is used to verify whether a port is open on a remote host?

- A. `netstat`
- B. `ip`
- **C. `nc`**
- D. `ping`

Answer: C

NEW QUESTION # 40

A systems administrator is configuring new Linux systems and needs to enable passwordless authentication between two of the servers. Which of the following commands should the administrator use?

- A. `ssh-agent -i rsa && ssh-copy-id ~/.ssh/key john@server2`
- B. `ssh-keyscan -t rsa && ssh-copy-id john@server2 -i ~/.ssh/key`
- **C. `ssh-keygen -t rsa && ssh-copy-id -i ~/.ssh/id_rsa.pub john@server2`**
- D. `ssh-add -t rsa && scp -rp ~/.ssh john@server2`

Answer: C

Explanation:

This command generates an SSH key pair and securely copies the public key to the remote server, enabling passwordless authentication by allowing key-based SSH login between the systems.

NEW QUESTION # 41

A new drive was recently added to a Linux system. Using the environment and tokens provided, complete the following tasks:

- * Create an appropriate device label.
- * Format and create an ext4 file system on the new partition.

The current working directory is /.
