What's more, PassLeaderVCE practice test materials have a high hit rate. 100% satisfaction guarantee! As well as you memorize these questions and answers in our dumps, you must pass CompTIA SY0-701 certification.

CompTIA Security+ Certification Exam Sample Questions (Q217-Q222):

NEW QUESTION # 217

An administrator learns that users are receiving large quantities of unsolicited messages. The administrator checks the content filter and sees hundreds of messages sent to multiple users. Which of the following best describes this kind of attack?

- A. Typosquatting
- B. Phishing
- C. Watering hole
- D. Business email compromise

Answer: B

Explanation:

The scenario describes a large number of unsolicited emails sent to multiple users. This is characteristic of phishing, which SY0-701 defines as mass-distributed fraudulent messages designed to trick recipients into clicking malicious links, downloading malware, or divulging sensitive information.

Phishing campaigns typically involve:

- * High volume
- * Non-targeted messaging
- * Use of spoofed addresses or fake content
- * Delivery through email systems

A watering-hole attack (A) compromises a legitimate website frequented by targets-not email.

Typosquatting (B) relies on malicious websites with deceptive URLs. Business Email Compromise (C) involves highly targeted spear-phishing or impersonation attacks, not bulk email blasts.

Because this incident involves "hundreds of messages" delivered to "multiple users," it clearly matches the characteristics of a phishing attack, not a sophisticated targeted attack type.

Phishing is the most common form of social engineering and is emphasized heavily in the Security+ exam due to its frequency and effectiveness.

NEW QUESTION # 218

Which of the following should a systems administrator use to decrease the company's hardware attack surface?

- A. Centralization
- B. Replication
- C. Isolation
- **D. Virtualization**

Answer: D

Explanation:

Virtualization (D) allows multiple systems and services to be hosted on fewer physical machines, thereby reducing the total number of physical devices and consequently the hardware attack surface. This also allows for better patching, monitoring, and control. The fewer devices you manage physically, the fewer entry points there are for attackers to exploit hardware-level vulnerabilities.

NEW QUESTION # 219

An organization is adopting cloud services at a rapid pace and now has multiple SaaS applications in use.

Each application has a separate log-in, so the security team wants to reduce the number of credentials each employee must maintain. Which of the following is the first step the security team should take?

- A. Enable SAML
- B. Create OAuth tokens.
- C. Use password vaulting
- **D. Select an IdP**

Answer: D

Explanation:

The first step in reducing the number of credentials each employee must maintain when using multiple SaaS applications is to select an Identity Provider (IdP). An IdP provides a centralized authentication service that supports Single Sign-On (SSO), enabling users to access multiple applications with a single set of credentials.

* Enabling SAML would be part of the technical implementation but comes after selecting an IdP.

* OAuth tokens are used for authorization, but selecting an IdP is the first step in managing authentication.

* Password vaulting stores multiple passwords securely but doesn't reduce the need for separate logins.

NEW QUESTION # 220

A systems administrator works for a local hospital and needs to ensure patient data is protected and secure.

Which of the following data classifications should be used to secure patient data?

- A. Critical
- **B. Sensitive**
- C. Public
- D. Private

Answer: B

Explanation:

Data classification is a process of categorizing data based on its level of sensitivity, value, and impact to the organization if compromised. Data classification helps to determine the appropriate security controls and policies to protect the data from unauthorized access, disclosure, or modification. Different organizations may use different data classification schemes, but a common one is the four-tier model, which consists of the following categories: public, private, sensitive, and critical.

Public data is data that is intended for public access and disclosure, and has no impact to the organization if compromised. Examples of public data include marketing materials, press releases, and public web pages.

Private data is data that is intended for internal use only, and has a low to moderate impact to the organization if compromised.

Examples of private data include employee records, financial reports, and internal policies.

Sensitive data is data that is intended for authorized use only, and has a high impact to the organization if compromised. Examples of sensitive data include personal information, health records, and intellectual property.

Critical data is data that is essential for the organization's operations and survival, and has a severe impact to the organization if compromised. Examples of critical data include encryption keys, disaster recovery plans, and system backups.

Patient data is a type of sensitive data, as it contains personal and health information that is protected by law and ethical standards.

Patient data should be used only by authorized personnel for legitimate purposes, and should be secured from unauthorized access, disclosure, or modification. Therefore, the systems administrator should use the sensitive data classification to secure patient data.

NEW QUESTION # 221

Which of the following describes the reason root cause analysis should be conducted as part of incident response?

- A. To prevent future incidents of the same nature
- B. To eradicate any trace of malware on the network
- C. To discover which systems have been affected
- D. To gather IoCs for the investigation

Answer: A

Explanation:

Root cause analysis is a process of identifying and resolving the underlying factors that led to an incident. By conducting root cause analysis as part of incident response, security professionals can learn from the incident and implement corrective actions to prevent future incidents of the same nature. For example, if the root cause of a data breach was a weak password policy, the security team can enforce a stronger password policy and educate users on the importance of password security. Root cause analysis can also help to improve security processes, policies, and procedures, and to enhance security awareness and culture within the organization. Root cause analysis is not meant to gather IoCs (indicators of compromise) for the investigation, as this is a task performed during the identification and analysis phases of incident response. Root cause analysis is also not meant to discover which systems have been affected or to eradicate any trace of malware on the network, as these are tasks performed during the containment and eradication phases of incident response.
