### NEW QUESTION # 75

What takes place during an SRDF Restore operation?

- A. Enables access to both the R1 and R2 devices for their hosts
- B. Changes made to the R2 are propagated to the R1. Changes made to the R1 are discarded
- C. Changes made to the R1 are propagated to the R2. Changes made to the R2 are discarded
- D. Resumes normal SRDF mirroring and host access

**Answer: C**

Explanation:

Step by Step Comprehensive Detailed Explanation:

In SRDF (Symmetrix Remote Data Facility), a "Restore" operation is used to resynchronize the source (R1) and target (R2) devices after a situation where the target device might have been modified independently. This typically occurs after a failover scenario where the target device becomes the primary and undergoes changes.

During an SRDF Restore operation:

\* R2 Changes Discarded: Any changes made to the target (R2) device since the last synchronization are discarded.

\* R1 Changes Propagated: The current data on the source (R1) device is copied over to the target (R2), overwriting any existing data on the target.

This effectively restores the target device to a state consistent with the source device, ensuring data integrity and consistency.

Why other options are incorrect:

\* B. Resumes normal SRDF mirroring and host access: While a Restore operation can be part of the failback process, it's not the only step involved. Failback might involve additional actions like reversing replication direction and restoring host access.

\* C. Changes made to the R2 are propagated to the R1. Changes made to the R1 are discarded: This describes an "Update" operation, not a "Restore."

\* D. Enables access to both the R1 and R2 devices for their hosts: This describes a "Split" operation, where both devices are made accessible independently.
