CompTIA PenTest+ Exam Sample Questions (Q23-Q28):

NEW QUESTION # 23

A penetration tester writes the following script to enumerate a 1724 network:

```
1 #!/bin/bash
2 for i in {1..254}; do
3 ping -c1 192.168.1.$i
4 done
```

The tester executes the script, but it fails with the following error:

-bash: syntax error near unexpected token `ping'

Which of the following should the tester do to fix the error?

- A. Add do after line 2.
- B. Replace bash with tsh.
- C. Replace {1..254} with \$(seq 1 254).
- D. Replace \$i with \${i}.

Answer: C

Explanation:

The syntax {1..254} is incorrect in Bash, as it uses brace expansion or seq for looping. The correct syntax should be:

for i in \$(seq 1 254)

Also, the missing do is an issue, but the syntax error mentioned points specifically to the loop structure.

Fixing the sequence format resolves it.

Corrected script:

```
#!/bin/bash
for i in $(seq 1 254); do
ping -c1 192.168.1.$i
done
```

From the CompTIA PenTest+ PT0-003 Official Study Guide (Chapter 4 - Scanning & Enumeration):

"Bash scripting is commonly used for automation in enumeration. The 'seq' command generates a sequence of numbers for iteration in loops."

NEW QUESTION # 24

Which of the following tasks would ensure the key outputs from a penetration test are not lost as part of the cleanup and restoration activities?

- A. Keeping chain of custody
- B. Exporting credential data
- C. Preserving artifacts
- D. Reverting configuration changes

Answer: C

Explanation:

Preserving artifacts ensures that key outputs from the penetration test, such as logs, screenshots, captured data, and any generated reports, are retained for analysis, reporting, and future reference.

NEW QUESTION # 25

In a file stored in an unprotected source code repository, a penetration tester discovers the following line of code:

```
sshpass -p donotchange ssh admin@192.168.6.14
```

Which of the following should the tester attempt to do next to take advantage of this information?

(Select two).

- A. Use an external exploit through Metasploit to compromise host 192.168.6.14.
- B. Run a password-spraying attack with Hydra against all the SSH servers.
- C. Confirm whether the server 192.168.6.14 is up by sending ICMP probes.
- D. Use Nmap to identify all the SSH systems active on the network.
- E. Investigate to find whether other files containing embedded passwords are in the code repository.
- F. Take a screen capture of the source code repository for documentation purposes.

Answer: E,F

Explanation:

When a penetration tester discovers hard-coded credentials in a file within an unprotected source code repository, the next steps should focus on documentation and further investigation to identify additional security issues.

Taking a Screen Capture (Option B):

Documentation: It is essential to document the finding for the final report. A screen capture provides concrete evidence of the discovered hard-coded credentials.

Audit Trail: This ensures that there is a record of the vulnerability and can be used to communicate the issue to stakeholders, such as the development team or the client.

Investigating for Other Embedded Passwords (Option C):

Thorough Search: Finding one hard-coded password suggests there might be others. A thorough investigation can reveal additional credentials, which could further compromise the security of the system.

Automation Tools: Tools like truffleHog, git-secrets, and grep can be used to scan the repository for other instances of hard-coded secrets.

NEW QUESTION # 26

A penetration tester gains access to a domain server and wants to enumerate the systems within the domain.

Which of the following tools would provide the best oversight of domains?

- A. Nmap
- B. Netcat
- C. Responder
- D. Wireshark

Answer: A

Explanation:

* Installation:

* Nmap can be installed on various operating systems. For example, on a Debian-based system:

```
sudo apt-get install nmap
```

* Basic Network Scanning:

* To scan a range of IP addresses in the network:

```
nmap -sP 192.168.1.0/24
```

* Service and Version Detection:

* To scan for open ports and detect the service versions running on a specific host:

```
nmap -sV 192.168.1.10
```

* Enumerating Domain Systems:

* Use Nmap with additional scripts to enumerate domain systems. For example, using the --script option:

```
nmap -p 445 --script=smb-enum-domains 192.168.1.10
```

* Advanced Scanning Options:

* Stealth Scan: Use the -sS option to perform a stealth scan:

```
nmap -sS 192.168.1.10
```

* Aggressive Scan: Use the -A option to enable OS detection, version detection, script scanning, and traceroute:

```
nmap -A 192.168.1.10
```

* Real-World Example:

* A penetration tester uses Nmap to enumerate the systems within a domain by scanning the network for live hosts and identifying the services running on each host. This information helps in identifying potential vulnerabilities and entry points for further exploitation.

* References from Pentesting Literature:

* In "Penetration Testing - A Hands-on Introduction to Hacking," Nmap is extensively discussed for various stages of the penetration testing process, from reconnaissance to vulnerability assessment.

* HTB write-ups often illustrate the use of Nmap for network enumeration and discovering potential attack vectors.

NEW QUESTION # 27

A penetration tester is conducting a vulnerability scan. The tester wants to see any vulnerabilities that may be visible from outside of the organization. Which of the following scans should the penetration tester perform?

- A. Sidecar
- B. SAST
- C. Host-based
- D. Unauthenticated

Answer: D

Explanation:

To see any vulnerabilities that may be visible from outside of the organization, the penetration tester should perform an unauthenticated scan.

Unauthenticated Scan:

Definition: An unauthenticated scan is conducted without providing any credentials to the scanning tool. It simulates the perspective of an external attacker who does not have any prior access to the system.

Purpose: Identifies vulnerabilities that are exposed to the public and can be exploited without authentication.

This includes open ports, outdated software, and misconfigurations visible to the outside world.

Comparison with Other Scans:

SAST (Static Application Security Testing): Analyzes source code for vulnerabilities, typically used during the development phase and not suitable for external vulnerability scanning.

Sidecar: This term is generally associated with microservices architecture and is not relevant to the context of vulnerability scanning.

Host-based: Involves scanning from within the network and often requires authenticated access to the host to identify vulnerabilities. It is not suitable for determining external vulnerabilities.

Pentest References:

External Vulnerability Assessment: Conducting unauthenticated scans helps identify the attack surface exposed to external threats and prioritizes vulnerabilities that are accessible from the internet.

Tools: Common tools for unauthenticated scanning include Nessus, OpenVAS, and Nmap.

By performing an unauthenticated scan, the penetration tester can identify vulnerabilities that an external attacker could exploit without needing any credentials or internal access.
