CompTIA A+ certification is a vendor-neutral certification, which means that it is not tied to a specific technology or vendor. CompTIA A+ Certification Exam: Core 2 certification is designed to provide individuals with the skills and knowledge needed to support IT infrastructures in a variety of settings. CompTIA A+ Certification Exam: Core 2 certification is divided into two exams: 220-1001 and 220-1002. The 220-1001 exam covers hardware, networking, mobile devices, and cloud computing, while the 220-1002 exam covers operating systems, security, and operational procedures.

CompTIA A+ Certification Exam: Core 2 Sample Questions (Q268-Q273):

NEW QUESTION # 268

A customer service representative is unable to send jobs to a printer at a remote branch office. However, the representative can print successfully to a local network printer. Which of the following commands should a technician use to view the path of the network traffic from the PC?

- A. format
- B. tracert
- C. netstat
- D. ping

Answer: B

Explanation:

The "tracert" command is used to view the path that network traffic takes from a PC to a specified destination. It is helpful in identifying where along the path the traffic may be failing or experiencing delays. In the scenario where a customer service representative can't send jobs to a remote printer but can print locally, "tracert" can help diagnose if there's a network routing issue affecting the connection to the remote branch office.

NEW QUESTION # 269

Which of the following should be enabled on a mobile device to prevent unauthorized access to data in case the device is lost or stolen? (Select two).

- A. VPN access
- **B. Biometric authentication**
- C. Antivirus software
- **D. Encryption**
- E. Remote wipe
- F. Device tracking

Answer: B,D

Explanation:

To prevent unauthorized access to data if a mobile device is lost or stolen, enabling biometric authentication (such as fingerprint or facial recognition) ensures only authorized users can unlock the device. Encryption protects stored data by making it unreadable without proper credentials, securing the device contents even if physically accessed. Remote wipe and device tracking assist in device recovery or data removal but do not directly prevent unauthorized access. Antivirus software and VPN access protect against malware and network threats but do not guard against physical access. Core 2 Security objectives emphasize biometric authentication and encryption as key security controls for mobile devices.

NEW QUESTION # 270

An engineer is configuring a new server that requires a bare-metal installation. Which of the following installation methods should the engineer use if installation media is not available on site?

- A. Recovery partition installation
- B. Repair installation
- **C. Remote network installation**
- D. Image deployment

Answer: C

Explanation:

Explanation

Remote network installation is the best option for configuring a new server that requires a bare-metal installation without installation media on site. A remote network installation is a method of installing an operating system or an application over a network connection, such as LAN, WAN, or Internet. A remote network installation can use various protocols, such as PXE, HTTP, FTP, or SMB, to access the installation files from a server or a cloud service. A remote network installation can also use various tools, such as Windows Deployment Services, Microsoft Deployment Toolkit, or Red Hat Kickstart, to automate and customize the installation process. A remote network installation can save time and resources by eliminating the need for physical media and allowing centralized management of multiple installations. Image deployment, recovery partition installation, and repair installation are not correct answers for this question. Image deployment is a method of installing an operating system or an application by copying a preconfigured image file to a target device. Image deployment requires an existing image file and a compatible device. Recovery partition installation is a method of restoring an operating system or an application from a hidden partition on the hard disk that contains the original factory settings. Recovery partition installation requires an existing recovery partition and a functional hard disk. Repair installation is a method of fixing an operating system or an application that is corrupted or damaged by replacing or repairing the system files without affecting the user data or settings. Repair installation requires an existing operating system or application and a working device. References:

NEW QUESTION # 271

Which of the following is the best reason for sandbox testing in change management?

* To evaluate the change before deployment

- A. To obtain end-user acceptance
- B. To determine the affected systems
- C. To select a change owner

Answer: A

Explanation:

Sandbox testing is a method of testing changes in a simulated environment that mimics the real one, without affecting the actual production system. Sandbox testing is useful for change management because it allows the testers to evaluate the change before deployment, and ensure that it works as intended, does not cause any errors or conflicts, and meets the requirements and expectations of the stakeholders. Sandbox testing also helps to protect the investment in the existing system, as it reduces the risk of introducing bugs or breaking functionality that could harm the customer experience or the business operations. Sandbox testing also gives the testers more control over the customer experience, as they can experiment with different scenarios and configurations, and optimize the change for the best possible outcome.

NEW QUESTION # 272

A technician is investigating options to secure a small office's wireless network. One requirement is to allow automatic log-ins to the network using certificates instead of passwords. Which of the following should the wireless solution have in order to support this feature?

- A. RADIUS
- B. MFA
- C. AES
- D. EAP-EKE

Answer: A

Explanation:

RADIUS is the correct answer for this question. RADIUS stands for Remote Authentication Dial-In User Service, and it is a protocol that provides centralized authentication, authorization, and accounting for wireless networks. RADIUS can support certificate-based authentication, which allows users to log in to the network automatically without entering passwords. RADIUS also provides other benefits, such as enforcing security policies, logging user activities, and managing network access. AES, EAP-EKE, and MFA are not wireless solutions, but rather encryption algorithms, authentication methods, and security factors, respectively.
