

# Python Institute PCEP-30-02 for the latest training materials

P.S. Free 2026 Python Institute PCEP-30-02 dumps are available on Google Drive shared by Real4Prep:  
[https://drive.google.com/open?id=15YVNHZWFbgs5\\_QaJVPbKuzOiSb6HdNij](https://drive.google.com/open?id=15YVNHZWFbgs5_QaJVPbKuzOiSb6HdNij)

Are you preparing for the PCEP-30-02 exam certification recently? Do you want to get a high score in the PCEP-30-02 actual test? Real4Prep PCEP-30-02 practice test may be the right study material for you. When you choose Python Institute PCEP-30-02 pdf dumps, you can download it and install it on your phone or i-pad, thus you can make full use of your spare time, such as, take the subway or wait for the bus. Besides, if you are tired of the electronic screen, you can print the PCEP-30-02 Pdf Dumps into papers, which is convenient to make notes.

## Python Institute PCEP-30-02 Exam Syllabus Topics:

Topic	Details
Topic 1	<ul style="list-style-type: none"><li>Control Flow: This section covers conditional statements such as if, if-else, if-elif, if-elif-else</li></ul>
Topic 2	<ul style="list-style-type: none"><li>Computer Programming Fundamentals: This section of the exam covers fundamental concepts such as interpreters, compilers, syntax, and semantics. It covers Python basics: keywords, instructions, indentation, comments in addition to Booleans, integers, floats, strings, and Variables, and naming conventions. Finally, it covers arithmetic, string assignment, bitwise, Boolean, relational, and Input</li><li>output operations.</li></ul>
Topic 3	<ul style="list-style-type: none"><li>Loops: while, for, range(), loops control, and nesting of loops.</li></ul>

## PCEP-30-02 Pass4sure & PCEP-30-02 Test Dumps Pdf

As we know, Python Institute actual test is related to the IT professional knowledge and experience, it is not easy to clear PCEP-30-02 practice exam. The difficulty of exam and the lack of time reduce your pass rate. And it will be a great loss for you if you got a bad result in the PCEP-30-02 Exam Tests. So it is urgent for you to choose a study appliance, especially for most people participating PCEP-30-02 real exam first time.

### Python Institute PCEP - Certified Entry-Level Python Programmer Sample Questions (Q42-Q47):

#### NEW QUESTION # 42

What is the expected result of the following code?

□

- A. The code will cause an unhandled
- B. 0
- C. 1
- D. 2

**Answer: A**

Explanation:

The code snippet that you have sent is trying to use a list comprehension to create a new list from an existing list. The code is as follows:

```
my_list = [1, 2, 3, 4, 5] new_list = [x for x in my_list if x > 5]
```

The code starts with creating a list called "my\_list" that contains the numbers 1, 2, 3, 4, and 5. Then, it tries to create a new list called "new\_list" by using a list comprehension. A list comprehension is a concise way of creating a new list from an existing list by applying some expression or condition to each element. The syntax of a list comprehension is:

```
new_list = [expression for element in old_list if condition]
```

The expression is the value that will be added to the new list, which can be the same as the element or a modified version of it. The element is the variable that takes each value from the old list. The condition is an optional filter that determines which elements will be included in the new list. For example, the following list comprehension creates a new list that contains the squares of the even numbers from the old list:

```
old_list = [1, 2, 3, 4, 5, 6] new_list = [x ** 2 for x in old_list if x % 2 == 0] new_list = [4, 16, 36]
```

The code that you have sent is trying to create a new list that contains the elements from the old list that are greater than 5. However, there is a problem with this code. The problem is that none of the elements in the old list are greater than 5, so the condition is always false. This means that the new list will be empty, and the expression will never be evaluated. However, the expression is not valid, because it uses the variable x without defining it. This will cause a NameError exception, which is an error that occurs when a variable name is not found in the current scope. The code does not handle the exception, and therefore it will terminate with an error message.

The expected result of the code is an unhandled exception, because the code tries to use an undefined variable in an expression that is never executed. Therefore, the correct answer is D. The code will cause an unhandled exception.

#### NEW QUESTION # 43

What is the expected output of the following code?

□

- A. 0
- B. 1
- C. 2
- D. The code outputs nothing.

**Answer: C**

Explanation:

The code snippet that you have sent is checking if two numbers are equal and printing the result. The code is as follows:

```
num1 = 1 num2 = 2 if num1 == num2: print(4) else: print(1)
```

The code starts with assigning the values 1 and 2 to the variables "num1" and "num2" respectively. Then, it enters an if statement that compares the values of "num1" and "num2" using the equality operator (==). If the values are equal, the code prints 4 to the screen. If the values are not equal, the code prints 1 to the screen.

The expected output of the code is 1, because the values of "num1" and "num2" are not equal. Therefore, the correct answer is C. 1.

#### NEW QUESTION # 44

What is the expected result of the following code?

□

- A. 0
- **B. The code is erroneous and cannot be run.**
- C. 1
- D. 2

**Answer: B**

Explanation:

Explanation

The code snippet that you have sent is trying to use the global keyword to access and modify a global variable inside a function. The code is as follows:

```
speed = 10 def velocity(): global speed speed = speed + 10 return speed print(velocity())
```

The code starts with creating a global variable called "speed" and assigning it the value 10. A global variable is a variable that is defined outside any function and can be accessed by any part of the code. Then, the code defines a function called "velocity" that takes no parameters and returns the value of "speed" after adding 10 to it. Inside the function, the code uses the global keyword to declare that it wants to use the global variable

"speed", not a local one. A local variable is a variable that is defined inside a function and can only be accessed by that function. The global keyword allows the function to modify the global variable, not just read it. Then, the code adds 10 to the value of "speed" and returns it. Finally, the code calls the function "velocity" and prints the result.

However, the code has a problem. The problem is that the code uses the global keyword inside the function, but not outside. The global keyword is only needed when you want to modify a global variable inside a function, not when you want to create or access it outside a function. If you use the global keyword outside a function, you will get a SyntaxError exception, which is an error that occurs when the code does not follow the rules of the Python language. The code does not handle the exception, and therefore it will terminate with an error message.

The expected result of the code is an unhandled exception, because the code uses the global keyword incorrectly. Therefore, the correct answer is A. The code is erroneous and cannot be run.

#### NEW QUESTION # 45

What is the expected output of the following code?

□

- **A. \* \***
- B. \* \* \*
- C. The code produces no output.
- D. \*

**Answer: A**

Explanation:

Explanation

The code snippet that you have sent is a conditional statement that checks if a variable "counter" is less than 0, greater than or equal to 42, or neither. The code is as follows:

```
if counter < 0: print("") elif counter >= 42: print("") else: print("")
```

The code starts with checking if the value of "counter" is less than 0. If yes, it prints a single asterisk ( ) to the screen and exits the statement. If no, it checks if the value of "counter" is greater than or equal to 42. If yes, it prints three asterisks ( ) to the screen and exits the statement. If no, it prints two asterisks ( ) to the screen and exits the statement.

The expected output of the code depends on the value of "counter". If the value of "counter" is 10, as shown in the image, the code will print two asterisks (\*\*) to the screen, because 10 is neither less than 0 nor greater than or equal to 42. Therefore, the correct answer is C. \* \*

#### NEW QUESTION # 46

What is true about exceptions and debugging? (Select two answers.)

- A. The default (anonymous) except branch cannot be the last branch in the try-except block.
- **B. One try-except block may contain more than one except branch.**
- C. If some Python code is executed without errors, this proves that there are no errors in it.
- **D. A tool that allows you to precisely trace program execution is called a debugger.**

**Answer: B,D**

Explanation:

Exceptions and debugging are two important concepts in Python programming that are related to handling and preventing errors. Exceptions are errors that occur when the code cannot be executed properly, such as syntax errors, type errors, index errors, etc. Debugging is the process of finding and fixing errors in the code, using various tools and techniques. Some of the facts about exceptions and debugging are:

\* A tool that allows you to precisely trace program execution is called a debugger. A debugger is a program that can run another program step by step, inspect the values of variables, set breakpoints, evaluate expressions, etc. A debugger can help you find the source and cause of an error, and test possible solutions. Python has a built-in debugger module called pdb, which can be used from the command line or within the code. There are also other third-party debuggers available for Python, such as PyCharm, Visual Studio Code, etc<sup>12</sup>

\* If some Python code is executed without errors, this does not prove that there are no errors in it. It only means that the code did not encounter any exceptions that would stop the execution. However, the code may still have logical errors, which are errors that cause the code to produce incorrect or unexpected results. For example, if you write a function that is supposed to calculate the area of a circle, but you use the wrong formula, the code may run without errors, but it will give you the wrong answer. Logical errors are harder to detect and debug than syntax or runtime errors, because they do not generate any error messages. You have to test the code with different inputs and outputs, and compare them with the expected results<sup>34</sup>

\* One try-except block may contain more than one except branch. A try-except block is a way of handling exceptions in Python, by using the keywords try and except. The try block contains the code that may raise an exception, and the except block contains the code that will execute if an exception occurs. You can have multiple except blocks for different types of exceptions, or for different actions to take. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except ZeroDivisionError: # handle the ZeroDivisionError exception
except: # handle any other exception
This way, you can customize the error handling for different situations, and provide more informative messages or alternative solutions5
```

\* The default (anonymous) except branch can be the last branch in the try-except block. The default except branch is the one that does not specify any exception type, and it will catch any exception that is not handled by the previous except branches. The default except branch can be the last branch in the try- except block, but it cannot be the first or the only branch. For example, you can write a try-except block like this:

```
try: # some code that may raise an exception
except ValueError: # handle the ValueError exception
except: # handle any other exception
This is a valid try-except block, and the default except branch will be the last branch. However, you cannot write a try-except block like this:
```

```
try: # some code that may raise an exception
except: # handle any exception
This is an invalid try-except block, because the default except branch is the only branch, and it will catch all exceptions, even those that are not errors, such as KeyboardInterrupt or SystemExit. This is considered a bad practice, because it may hide or ignore important exceptions that should be handled differently or propagated further. Therefore, you should always specify the exception types that you want to handle, and use the default except branch only as a last resort5 Therefore, the correct answers are A. A tool that allows you to precisely trace program execution is called a debugger. and C. One try-except block may contain more than one except branch.
```
