EMC Dell PowerFlex Operate Exam Sample Questions (Q51-Q56):

NEW QUESTION # 51

Enabling Maintenance Mode on a node allows it to be removed from the cluster without impacting data availability. True. False.

- A. True
- B. False

Answer: A

Explanation:

* True: The specific purpose of Protected Maintenance Mode (PMM) is to ensure data availability.

* How it works: When you enable PMM on a node, the system checks the data chunks residing on that node. Before the node is allowed to effectively "leave" the cluster (stop serving I/O), PowerFlex copies (mirrors) that data to other nodes in the cluster. This ensures that even when the node is physically removed or rebooted, the cluster retains the required number of data copies (redundancy), ensuring no data is unavailable (DU) or lost (DL).

NEW QUESTION # 52

An administrator wants to configure a shared file system in PowerFlex. What steps should they follow? (Select two).

- A. Assign the file system to a protection domain
- **B. Configure multi-node access permissions**
- C. Validate compatibility with all nodes in the cluster
- **D. Create the shared file system using the GUI**

Answer: B,D

Explanation:

Configuring PowerFlex File (NAS) involves creating the logical file system and then defining how clients access it.

* Create the shared file system using the GUI (Option A): The administrator uses the PowerFlex Manager (or Block UI) to define the file system properties, such as name, size, and the Storage Pool it will consume capacity from.

* Configure multi-node access permissions (Option C): Once the file system exists, it is not accessible until it is "Exported" (NFS) or "Shared" (SMB). During this step, the administrator must configure the access control lists (ACLs) or export policies that define which client IPs or Subnets (nodes) are allowed to mount the file system and whether they have Read-Only or Read-Write permissions.

NEW QUESTION # 53

What actions can administrators perform to manage PowerFlex shared file systems? (Choose two).

- A. Assign file systems to fault sets
- **B. Enable data access for multiple nodes**
- **C. Configure snapshots for shared file systems**
- D. Deduplicate shared file system data

Answer: B,C

Explanation:

PowerFlex File (NAS) extends the block capabilities to support file-level access.

* Enable data access for multiple nodes (Option B): The fundamental purpose of a shared file system (NAS) is to allow multiple clients (Linux via NFS, Windows via SMB) to access the same dataset simultaneously over the network. PowerFlex File manages the exports and shares that facilitate this concurrency.

* Configure snapshots for shared file systems (Option C): Just like block volumes, PowerFlex File systems support snapshots. These file-system level snapshots allow users to recover deleted files or administrators to roll back the entire file system to a previous point in time.

Incorrect Options:

* Assign file systems to fault sets (A): Fault Sets are a block-layer construct for physical SDS nodes. File systems are logical entities that reside on the storage provided by the block layer; they are not directly assigned to Fault Sets.

* Deduplicate shared file system data (D): Deduplication occurs at the underlying Storage Pool level (inline), not as a management action performed on a specific file system.

NEW QUESTION # 54

Which conditions must be met to begin a PowerFlex upgrade? (Choose two).

- **A. Cluster health status must be green**
- B. Metadata Managers must be active

- C. All nodes must be online
- D. All fault sets must be reconfigured

Answer: A,C

Explanation:

To ensure a successful and non-disruptive upgrade (NDU), the PowerFlex cluster must be in a stable and healthy state before the process begins.

- * Cluster health status must be green (Option B): This is the primary indicator. A "Green" health state implies that there are no critical errors, no rebuilds or rebalances in progress, and sufficient capacity is available. If the cluster is in a "Red" (Critical) or "Orange" (Degraded) state, the upgrade wizard in PowerFlex Manager (or the CLI pre-check) will block the operation to prevent data loss.
- * All nodes must be online (Option A): All configured Storage Data Servers (SDS) and Metadata Managers (MDM) must be reachable. If a node is offline or disconnected, the orchestration engine cannot verify redundancy or place that node into maintenance mode safely.

Incorrect Options:

- * Reconfiguring Fault Sets (C) is a structural change, not a prerequisite for an upgrade.
- * Metadata Managers must be active (D) is technically true, but this is inherently covered by the "Green" health status; you cannot have a green cluster if MDMs are down.

NEW QUESTION # 55

What is the primary function of alerting in PowerFlex security?

- A. Configure multi-factor authentication
- B. Automate encryption key rotation
- C. Manage compliance baselines for devices
- D. Notify administrators of potential security issues

Answer: D

Explanation:

While "alerting" is a broad topic, in the context of security:

- * Notify administrators of potential security issues (Option B): The alerting system is designed to trigger notifications for security-relevant events. Examples include:
- * Failed Login Attempts: Repeated failures which might indicate a brute-force attack.
- * Unauthorized Access: Connections from unapproved IPs (if restrictions are set).
- * Certificate Expiry: Warning that SSL/TLS certificates are about to expire, which would break secure management connections.
- * Encryption Failures: Alerts if a SED drive is unlocked or CloudLink key retrieval fails.
