CompTIA A+ Core 1 Exam (2026) Sample Questions (Q60-Q65):

NEW QUESTION # 60

A small company recently added VoIP through its ISP. Users report intermittent call quality issues during peak hours. Which of the following steps should the IT administrator take to solve the issue?

- A. Install a shielded network cable.
- B. Increase the VoIP bit rate.
- C. Route calls through a gigabit port.
- D. Configure the VLAN to split services.

Answer: D

Explanation:

Intermittent VoIP call quality issues that occur during peak hours are a classic symptom of network congestion caused by voice and data traffic competing for the same network resources. According to CompTIA Core 1 (220-1201) networking and VoIP objectives, one of the most effective solutions is to configure VLANs to separate voice and data traffic.

By placing VoIP devices on a dedicated voice VLAN, the network can apply Quality of Service (QoS) policies that prioritize voice

packets over standard data traffic. This reduces latency, jitter, and packet loss, which are the primary causes of poor call quality. VLAN separation ensures that even during heavy data usage, voice traffic remains clear and reliable.

Routing calls through a gigabit port does not address traffic prioritization and is unlikely to resolve congestion during peak usage. Installing shielded network cables only helps in environments with excessive electromagnetic interference, which would affect performance consistently-not intermittently. Increasing the VoIP bit rate would actually worsen congestion by consuming more bandwidth.

CompTIA emphasizes VLAN implementation and QoS as best practices for VoIP deployments, especially when call quality degrades under high network utilization.

NEW QUESTION # 61

Which of the following devices is designed specifically to allow multiple network devices to communicate across a single platform?

- A. NIC
- **B. Switch**
- C. Firewall
- D. Routers

Answer: B

Explanation:

A switch is designed to connect multiple devices within the same local network so they can communicate efficiently. In a typical LAN, a switch provides multiple Ethernet ports and forwards traffic between connected devices by using MAC addresses. When a frame enters a switch port, the switch learns the source MAC address and associates it with that port in a MAC address table. When the destination MAC is known, the switch sends the frame only out the correct port, which reduces unnecessary traffic and improves performance compared to older hub-based networks. This is exactly what is meant by allowing multiple network devices to communicate "across a single platform" (the switching fabric).

A NIC is an adapter in an endpoint device that provides network connectivity, but it does not interconnect multiple devices by itself. A firewall focuses on filtering and controlling traffic based on security rules, not primarily on providing multi-device LAN connectivity. Routers connect different networks and forward traffic based on IP addresses (Layer 3), which is not the primary device for multi-device communication within the same network segment. Therefore, the correct answer is Switch.

NEW QUESTION # 62

Which of the following technologies best allows a phone to connect to a point-of-sale terminal for wireless payments?

- A. Cellular
- B. Wi-Fi
- **C. NFC**
- D. Bluetooth

Answer: C

Explanation:

Near-field communication (NFC) is a short-distance wireless communication method widely used in mobile payment systems like Apple Pay and Google Pay. Simply placing the device near a compatible terminal initiates the payment process.

NEW QUESTION # 63

Which of the following should a technician use to terminate a Cat 6 cable to a patch panel?

- A. Crimper
- **B. Punchdown tool**
- C. Network tap
- D. Toner probe

Answer: B

Explanation:

A punchdown tool is specifically used to insert wires into a punchdown block in patch panels, which is typical for Cat 6 and similar

cabling. It ensures a secure and correct connection by pushing the wire into a metal groove that slices the insulation.

NEW QUESTION # 64

A technician is troubleshooting a workstation that repeatedly shuts down within ten minutes of being turned on. The technician notices a loud clicking sound coming from inside the case. Which of the following components should the technician check first?

- A. Intake fan
- **B. CPU fan**
- C. Capacitors
- D. Exhaust fan

Answer: B

Explanation:

A failing CPU fan may make unusual noises (including clicking) and, if it is not cooling the CPU, the system will quickly overheat and shut down to prevent damage.

From CompTIA A+ 220-1101 Official Study Guide, Objective 4.1 - Troubleshooting hardware problems:

"Overheating due to a failed or obstructed CPU fan can cause frequent shutdowns. Loud noises are a sign the fan should be checked first." Verified Source:
