CompTIA Data+ Certification Exam Sample Questions (Q155-Q160):

NEW QUESTION # 155
Chris is building a database to store prices for items on a restaurant menu.
What data type is most appropriate for this field?

- A. Tags.
- B. Date.
- C. Alphanumeric.
- D. Numeric.

Answer: D

Explanation:

Prices are numbers stored in dollars and cents; as such, the data type needs to be capable of storing numbers.

NEW QUESTION # 156
A data analyst who works for a government agency is required to obtain the average income of citizens. The list of citizens is given in the following table:

Name	Age	Employed	Income
Scott	19	N	$0
Kim	39	Y	$150,000
John	50	Y	$200,000
Jessica	27	N	$0
James	38	Y	$150,000
Anne	22	Y	$35,000
Mike	37	N	$50,000
Margaret	25	Y	$60,000
Carl	31	Y	(Missing)
Diana	28	Y	$120,000

A value for one citizen's income is missing. Which of the following approaches should the data analyst take to solve this issue?

- A. Impute the mean of the other citizens' incomes into the field with the missing value.
- B. Exclude employed citizens from the analysis.
- C. Replace the missing value with the average of the rest of the unemployed citizens.
- D. Insert the value 0 into the field with the missing value.

Answer: A

Explanation:
Comprehensive and Detailed In-Depth Explanation:
Handling missing data is crucial for maintaining the integrity of an analysis. Since the missing value belongs to an employed individual, the most appropriate method is to impute the mean income of employed citizens.
* Option A (Replace the missing value with the average of unemployed citizens):Incorrect. The missing income is for an employed individual, so it would be inappropriate to use the unemployed citizens' average.
* Option B (Insert 0):Incorrect. Assigning 0 would be misleading since it does not reflect the income distribution for employed citizens.
* Option C (Impute the mean of the other citizens' incomes):Correct.A common practice in data analytics is mean imputation, where missing values are replaced with the mean of similar cases (in this case, other employed citizens).
* Option D (Exclude employed citizens from the analysis):Incorrect. This would remove valuable data and lead to biased results.

NEW QUESTION # 157
A data analyst needs to create a data visualization that aids in un the cumulative impact of sequentially introduced values that are positive or negative. Which of the following data visualization methods should the analyst use?

- A. A line chart
- B. A scatter plot
- C. A bubble chart
- D. A waterfall chart

Answer: D

Explanation:
Explanation

A waterfall chart is a type of data visualization that shows the cumulative impact of sequentially introduced values that are positive or negative. A waterfall chart typically has an initial value and a final value, with intermediate values shown as floating columns that either add to or subtract from the initial value. A waterfall chart can help visualize how different factors contribute to a net change in a value over time. Therefore, the correct answer is B. NEW QUESTION # 158
Which of the following would be the best way to identify multicollinear attributes in a data set?

- A. Two-sample f-test
- B. Two-way ANOVA
- C. Chi-squared test
- D. Correlation coefficient

Answer: D

Explanation:
Multicollinearity in a dataset refers to the situation where two or more predictor variables are highly correlated, meaning that one can be linearly predicted from the others with a substantial degree of accuracy.
In such cases, the correlation coefficient is a key statistical measure used to identify the presence of multicollinearity. It quantifies the degree to which two variables are linearly related.
The Variance Inflation Factor (VIF) is another commonly used metric that is derived from the correlation coefficient. It assesses how much the variance of an estimated regression coefficient increases if your predictors are correlated. If no factors are correlated, the VIFs will all be equal to 1.
While the other options listed-Chi-squared test, Two-sample f-test, and Two-way ANOVA-are valuable statistical tools, they serve different purposes and are not typically used to detect multicollinearity. The Chi- squared test is used for testing relationships between categorical variables, the Two-sample f-test compares variances across groups, and Two-way ANOVA is used to understand the interaction between two independent categorical variables on a continuous dependent variable.

NEW QUESTION # 159
Which of the following is a characteristic of a relational database?

- A. It uses minimal memory.
- B. It is structured in nature.
- C. It utilizes key-value pairs.
- D. It has undefined fields.

Answer: B

Explanation:
Explanation
It is structured in nature. This is because a relational database is a type of database that organizes data into tables, which consist of rows and columns. A relational database is structured in nature, which means that the data has a predefined schema or format, and follows certain rules and constraints, such as primary keys, foreign keys, or referential integrity. A relational database can be used to store, query, and manipulate data using a structured query language (SQL). The other characteristics are not true for a relational database. Here is why:
It utilizes key-value pairs. This is not true for a relational database, because key-value pairs are a way of storing data that associates each value with a unique key, such as an identifier or a name. Key-value pairs are typically used in non-relational databases, such as NoSQL databases, which do not have tables, rows, or columns, but rather store data in various formats, such as documents, graphs, or columns.
It has undefined fields. This is not true for a relational database, because fields are another name for columns in a table, which define the attributes or properties of each row or record in the table. Fields have defined names, types, and lengths in a relational database, which specify the format and size of the data that can be stored in each field.
It uses minimal memory. This is not true for a relational database, because memory is the amount of space or storage that is used by

a database to store and process data. Memory usage depends on various factors, such as the size, complexity, and number of tables and queries in a relational database. A relational database can use a lot of memory if it has many tables with many rows and columns, or if it performs complex or frequent queries on the data.
