Amazon AWS Certified Developer - Associate Sample Questions (Q598-Q603):

NEW QUESTION # 598

An application that is hosted on an Amazon EC2 instance needs access to files that are stored in an Amazon S3 bucket. The application lists the objects that are stored in the S3 bucket and displays a table to the user. During testing, a developer discovers that the application does not show any objects in the list.

What is the MOST secure way to resolve this issue?

- A. Update the developer's user permissions to include the S3:ListBucket permission for the S3 bucket.
- B. Update the IAM instance profile that is attached to the EC2 instance to include the S3:* permission for the S3 bucket.
- C. **Update the IAM instance profile that is attached to the EC2 instance to include the S3:ListBucket permission for the S3 bucket.**
- D. Update the S3 bucket policy by including the S3:ListBucket permission and by setting the Principal element to specify the account number of the EC2 instance.

Answer: C

NEW QUESTION # 599

A developer is testing a RESTful application that is deployed by using Amazon API Gateway and AWS Lambda. When the developer tests the user login by using credentials that are not valid, the developer receives an HTTP 405 METHOD_NOT_ALLOWED error. The developer has verified that the test is sending the correct request for the resource. Which HTTP error should the application return in response to the request?

- A. HTTP 503
- B. **HTTP 401**
- C. HTTP 505
- D. HTTP 404

Answer: B

Explanation:

* HTTP Status Codes: Each HTTP status code has a specific meaning in RESTful APIs.

* HTTP 405 (Method Not Allowed): Indicates that the request method (e.g., POST) is not supported for the specified resource.

* HTTP 401 (Unauthorized): Represents a failure to authenticate, which is the appropriate response for invalid login credentials.

NEW QUESTION # 600

A developer is creating an AWS Serverless Application Model (AWS SAM) template. The AWS SAM template contains the definition of multiple AWS Lambda functions, an Amazon S3 bucket, and an Amazon CloudFront distribution. One of the Lambda functions runs on Lambda@Edge in the CloudFront distribution. The S3 bucket is configured as an origin for the CloudFront distribution.

When the developer deploys the AWS SAM template in the eu-west-1 Region, the creation of the stack fails.

Which of the following could be the reason for this issue?

- A. **Lambda@Edge functions can be created only in the us-east-1 Region.**
- B. CloudFront distributions can be created only in the us-east-1 Region.
- C. A single AWS SAM template cannot contain multiple Lambda functions.
- D. The CloudFront distribution and the S3 bucket cannot be created in the same Region.

Answer: A

Explanation:

It must be deployed to a region where Lambda@Edge is supported, such as us-east-1.

NEW QUESTION # 601

A developer at a company writes an AWS CloudFormation template. The template refers to subnets that were created by a separate AWS CloudFormation template that the company's network team wrote. When the developer attempts to launch the stack for the first time, the launch fails.

Which template coding mistakes could have caused this failure? (Choose two.)

- A. The network team's template does not export the subnets in the `Mappings` section.
- B. The developer's template does not use the `Ref` intrinsic function to refer to the subnets.
- C. The developer's template does not use the `ImportValue` intrinsic function to refer to the subnets.
- D. The `Mappings` section of the developer's template does not refer to the subnets.
- E. The network team's template does not export the subnets in the `Outputs` section.

Answer: C,E

NEW QUESTION # 602

A developer created an AWS Lambda function to process data in an application. The function pulls large objects from an Amazon S3 bucket, processes the data, and loads the processed data into a second S3 bucket. Application users have reported slow response times. The developer checks the logs and finds that Lambda function invocations run much slower than expected. The function itself is simple and has a small deployment package. The function initializes quickly. The developer needs to improve the performance of the application. Which solution will meet this requirement with the LEAST operational overhead?

- A. Create an Amazon EventBridge rule to schedule invocations of the function every minute.
- B. Create a Lambda layer to package the function dependencies. Add the layer to the function.
- C. Store the data in an Amazon EFS file system. Mount the file system to a local directory in the function.
- D. Configure the function to use ephemeral storage. Upload the objects and process data in the `/tmp` directory.

Answer: D

Explanation:

Configuring the Lambda function to use ephemeral storage and processing data in the `/tmp` directory improves performance by leveraging local storage during execution.

Why Option C is Correct:

Ephemeral Storage: Lambda provides temporary storage (up to 10 GB) in the `/tmp` directory for each invocation, which is faster than pulling data directly from S3 multiple times.

Performance Boost: Data can be downloaded to `/tmp`, processed locally, and uploaded to the destination S3 bucket, minimizing S3 network calls.

Low Overhead: This approach requires only minimal changes to the function's configuration.

Why Not Other Options:

Option A: Using Amazon EFS adds complexity and is unnecessary for this use case.

Option B: Scheduling the function does not address the root cause of slow performance.

Option D: Lambda layers improve deployment efficiency, not runtime performance for this scenario.
