Um die Interessen zu schützen, bietet unsere Website die online Prüfungen zur CertNexus AIP-210 Zertifizierungsprüfung von EchteFrage, die von den erfahrungsreichen IT-Experten nach den Bedürfnissen bearbeitet werden. Sie werden Ihnen nicht nur helfen, die CertNexus AIP-210 Prüfung zu bestehen und auch eine bessere Zukunft zu haben.

Um in einer Branche immer an führender Stelle zu stehen, muss das Unternehmen seine eigene Ressourcen zu vermehren. Wir EchteFrage aktualisieren kontinuierlich die Test-Bank und die Softwaren. Deshalb können wir Ihnen garantieren, dass die CertNexus AIP-210 Prüfungssoftware, die Sie benutzen, enthält die neuesten und die umfassendsten Prüfungsunterlagen. In Welcher Vorbereitungsphase der CertNexus AIP-210 Prüfung immer Sie stehen, kann unsere Software Ihr bester Helfer sein, denn die Prüfungsunterlagen der CertNexus AIP-210 werden von dem erfahrenen und qualifiziertem IT Eliteteam geordnet und analysiert.

AIP-210 Trainingsmaterialien: CertNexus Certified Artificial Intelligence Practitioner (CAIP) & AIP-210 Lernmittel & CertNexus AIP-210 Quiz

Alle IT-Fachleute sind mit der CertNexus AIP-210 Zertifizierungsprüfung vertraut. Sie alle träumen davon, ein Zertifikat zu bekommen. Sie können Ihren Traum verwirklichen und eine gute Berufskarriere machen. Durch die Schulungsunterlagen zur CertNexus AIP-210 Zertifizierungsprüfung von EchteFrage können Sie bekommen, was Sie wollen.

CertNexus Certified Artificial Intelligence Practitioner (CAIP) AIP-210 Prüfungsfragen mit Lösungen (Q70-Q75):

70. Frage

A change in the relationship between the target variable and input features is

- A. data drift.
- **B. concept drift.**
- C. model decay.
- D. covariate shift.

Antwort: B

Begründung:

Explanation

Concept drift, also known as model drift, occurs when the task that the model was designed to perform changes over time. For example, imagine that a machine learning model was trained to detect spam emails based on the content of the email. If the types of spam emails that people receive change significantly, the model may no longer be able to accurately detect spam. References: Understanding Data Drift and Model Drift: Drift Detection in Python | DataCamp, Machine Learning Monitoring, Part 5: Why You Should Care About Data and Concept Drift

71. Frage

Given a feature set with rows that contain missing continuous values, and assuming the data is normally distributed, what is the best way to fill in these missing features?

- A. Delete entire rows that contain any missing features.
- B. Fill in missing features with random values for that feature in the training set.
- **C. Fill in missing features with the average of observed values for that feature in the entire dataset.**
- D. Delete entire columns that contain any missing features.

Antwort: C

Begründung:

Explanation

Missing values are a common problem in data analysis and machine learning, as they can affect the quality and reliability of the data and the model. There are various methods to deal with missing values, such as deleting, imputing, or ignoring them. One of the most common methods is imputing, which means replacing the missing values with some estimated values based on some criteria. For continuous variables, one of the simplest and most widely used imputation methods is to fill in the missing values with the mean (average) of the observed values for that variable in the entire dataset. This method can preserve the overall distribution and variance of the data, as well as avoid introducing bias or noise.

72. Frage

Your dependent variable Y is a count, ranging from 0 to infinity. Because Y is approximately log-normally distributed, you decide to log-transform the data prior to performing a linear regression.

What should you do before log-transforming Y?

- A. Explore the data for outliers.
- **B. Add 1 to all of the Y values.**
- C. Divide all the Y values by the standard deviation of Y.
- D. Subtract the mean of Y from all the Y values.

Antwort: B

Begründung:

Explanation

Before log-transforming Y, we should add 1 to all of the Y values. This is because log transformation is undefined for zero or negative values, and some of the Y values may be zero. Adding 1 to all of the Y values can avoid this problem and ensure that the log transformation is valid and meaningful. Adding 1 to all of the Y values is also known as a log-plus-one transformation.

73. Frage

A company is developing a merchandise sales application. The product team uses training data to teach the AI model predicting sales, and discovers emergent bias. What caused the biased results?

- A. The team set flawed expectations when training the model.
- B. The training data used was inaccurate.
- C. The application was migrated from on-premise to a public cloud.
- **D. The AI model was trained in winter and applied in summer.**

Antwort: D

Begründung:

Explanation

Emergent bias is a type of bias that arises when an AI model encounters new or different data or scenarios that were not present or accounted for during its training or development. Emergent bias can cause the model to make inaccurate or unfair predictions or decisions, as it may not be able to generalize well to new situations or adapt to changing conditions. One possible cause of emergent bias is seasonality, which means that some variables or patterns in the data may vary depending on the time of year. For example, if an AI model for merchandise sales prediction was trained in winter and applied in summer, it may produce biased results due to differences in customer behavior, demand, or preferences.

74. Frage

Word Embedding describes a task in natural language processing (NLP) where:

- A. Words are grouped together into clusters and then represented by word cluster membership.
- B. Words are featurized by taking a histogram of letter counts.
- **C. Words are converted into numerical vectors.**
- D. Words are featurized by taking a matrix of bigram counts.

Antwort: C

Begründung:

Explanation

Word embedding is a task in natural language processing (NLP) where words are converted into numerical vectors that represent their meaning, usage, or context. Word embedding can help reduce the dimensionality and sparsity of text data, as well as enable various operations and comparisons among words based on their vector representations. Some of the common methods for word embedding are:

One-hot encoding: One-hot encoding is a method that assigns a unique binary vector to each word in a vocabulary. The vector has only one element with a value of 1 (the hot bit) and the rest with a value of

0. One-hot encoding can create distinct and orthogonal vectors for each word, but it does not capture any semantic or syntactic information about words.

Word2vec: Word2vec is a method that learns a dense and continuous vector representation for each word based on its context in a large corpus of text. Word2vec can capture the semantic and syntactic similarity and relationships among words, such as synonyms, antonyms, analogies, or associations.

GloVe: GloVe (Global Vectors for Word Representation) is a method that combines the advantages of count-based methods (such as TF-IDF) and predictive methods (such as Word2vec) to create word vectors. GloVe can leverage both global and local information from a large corpus of text to capture the co-occurrence patterns and probabilities of words.
