### **WGU Introduction to IT Sample Questions (Q50-Q55):**

#### **NEW QUESTION # 50**

Which component of an operating system allows the operating system to run applications?

- A. User interface
- B. File manager
- **C. Kernel**
- D. Driver

**Answer: C**

Explanation:

The kernel is the core component of an operating system that enables applications to run by managing system resources and providing essential services. In Information Technology, applications do not directly control the CPU, memory, or hardware devices. Instead, they request services from the operating system through system calls, which are handled by the kernel. The kernel manages process creation and execution, memory allocation, multitasking, and communication between software and hardware. It also enforces protection and security boundaries so one program cannot easily interfere with another or with the operating system itself. The user interface affects how users interact with the system, but it is not the component that actually runs programs. The file manager handles organization and access to files, and drivers allow the operating system to communicate with specific hardware devices, such as printers and network cards. Because the kernel controls process execution and resource management, it is the operating system component that allows applications to run.

#### **NEW QUESTION # 51**

The primary database application used by a company is having issues, specifically with the layer that alters the database after receiving a request. What is the name of this layer of the database application?

- A. The object-oriented layer
- B. The application layer
- **C. The database management layer**
- D. The flat-file layer

**Answer: C**

Explanation:

The layer responsible for altering a database after receiving a request is the database management layer. In standard database architecture, the database management system acts as the software layer that processes requests, enforces rules, and performs operations such as insert, update, and delete. When an application or user submits a query or transaction, the database management layer interprets the request, checks permissions and constraints, manages concurrency so multiple users can work safely, and then applies changes to the stored data. It also helps ensure reliability through transaction controls such as commit and rollback, which protect data integrity when failures occur. The application layer is where the user interface and business logic typically run, but it

does not directly manage the physical storage and controlled updates of the database. The flat-file layer is not a standard layer in modern database applications, and object-oriented layer refers to a programming design style rather than the core DBMS component. Therefore, the correct layer is the database management layer.

#### NEW QUESTION # 52

Which software allows the user to easily access the hardware of a computer?

- A. Application
- B. FTP client
- C. Productivity
- **D. Operating system**

**Answer: D**

Explanation:

\*The software that allows the user to easily access the hardware of a computer is the operating system.

\*Explanation: The operating system serves as the interface between hardware, application software, and the user. It manages hardware resources, file systems, processes, and memory.

\*References: 12

Therefore, the correct answer is C. Operating system.

#### NEW QUESTION # 53

What is one of the factors that determines the choice of an operating system?

- A. Number of devices
- **B. Device type**
- C. Driver compatibility
- D. Coding language

**Answer: B**

Explanation:

One major factor that determines the choice of an operating system is the device type. Operating systems are designed for specific categories of hardware and usage environments, such as desktop computers, servers, mobile phones, tablets, embedded devices, and network appliances. In Information Technology fundamentals, selecting an operating system begins with identifying the platform requirements, including processor architecture, memory limits, battery needs, and how the device will be used. For example, iOS and Android are designed for mobile devices, Windows and macOS are designed for desktops and laptops, and server operating systems are tuned for reliability, remote administration, and multi-user workloads. While driver compatibility is also an important consideration, many curricula treat it as a sub-factor related to hardware support within a chosen device category. Number of devices relates more to licensing and deployment planning, and coding language is not a direct determinant of which operating system must be used. Therefore, device type is a correct factor in choosing an operating system.

#### NEW QUESTION # 54

A programmer needs to create a variable that holds a wire length rounded to the nearest tenth. What is the name of the data type that should be used?

- A. Character
- **B. Floating point**
- C. Character string
- D. Integer

**Answer: B**

Explanation:

A wire length rounded to the nearest tenth requires a numeric type that can store fractional values, such as 2.3 meters or 15.7 centimeters. In programming and database systems, floating-point data types are designed to represent real numbers that include decimal portions. This makes floating point the appropriate choice for measurements, scientific values, averages, and any quantity where partial units are meaningful. Using an integer would lose the fractional component because integers store only whole numbers,

which would make the rounded-to-the-tenth requirement impossible to preserve. Character and character string types store text symbols rather than numeric quantities intended for arithmetic and comparisons. In Information Technology curricula, floating-point types are often introduced alongside integers to highlight the difference between counting values and measurement values. Although some databases prefer fixed-point decimal types for financial precision, for a physical measurement like wire length, floating point is commonly accepted and matches the options provided. Therefore, the correct data type for a wire length rounded to the nearest tenth is floating point.
