Palo Alto Networks XSOAR Engineer Sample Questions (Q204-Q209):

NEW QUESTION # 204

What determines the current verdict for an indicator when multiple sources provide different reliability scores and verdicts?.

- A. Verdict provided by the most recently updated source.
- **B. Verdict provided by the source with the highest reliability score.**
- C. Average verdict score from all sources.
- D. Highest severity verdict from all sources.

Answer: B

Explanation:

The Threat Intelligence section specifies that XSOAR determines an indicator's verdict by selecting the verdict from the source that has the highest reliability score.

Only when two sources have equal reliability does XSOAR choose the most severe (worst) verdict between them.

NEW QUESTION # 205

What aggregates data from incidents and indicators into a Cortex XSOAR report?.

- A. SQL queries.
- B. Automations.
- **C. Widgets.**
- D. Playbooks.

Answer: C

Explanation:

In Cortex XSOAR, Reports are constructed from Widgets, which are modular visualization components that pull data from incidents, indicators, tasks, lists, and other system sources. The Admin Guide clarifies that widgets serve as the building blocks for dashboards and reports. When creating a report, users select widgets-such as pie charts, tables, statistics blocks, histograms, and custom scripts-and XSOAR aggregates the underlying data (incidents, indicators, evidence, etc.) into the report output.

Automations (option B) may generate data, but they do not perform the aggregation within a report. SQL queries (option C) are not used natively in XSOAR reporting; instead, widgets may embed queries through the platform's data model. Playbooks (option D) execute response workflows and can generate additional context but are not used for aggregating report data.

Thus, the report-generation process relies entirely on widgets to extract, sort, count, and visualize information.

XSOAR renders the report by collecting the aggregated values produced by each widget. This makes option A the correct and documented answer.

NEW QUESTION # 206

Previous playbook tasks have built out the context in the image below.

When specifying `${User.Name}` as an input for a sub-playbook task which has the default loop configuration, how many times will the sub-playbook be executed?.

- A. 0.
- **B. 4.**
- C. 1.
- D. 3.

Answer: B

NEW QUESTION # 207

Which two features does XSOAR offer to help recover from a server failure? (Choose two.)

- A. Local backup
- **B. Backup data to XSOAR engines**
- **C. Live backup (disaster recovery)**
- D. Distributed database

Answer: B,C

NEW QUESTION # 208

Which feature is used to convert event data values into incident fields when an integration fetches an event?.

- A. Layout configuration.
- B. Classification.
- C. Field configuration.
- **D. Mapping.**

Answer: D

Explanation:

XSOAR's ingestion pipeline defines a strict order in which raw fetched data is processed, and the Admin Guide explains that Classification determines the incident type based on incoming fields, while Mapping performs the actual transformation of event data into structured incident fields. Mapping profiles define how each field from the integration's raw JSON (for example, `source_ip`, `username`, `alert_id`) is converted into standard or custom incident fields.

The Mapping Editor allows administrators to select specific fields from the incoming event data and bind them to incident fields used throughout playbooks, layouts, and reports. This ensures normalization of data and consistent schema usage across the SOC.

The documentation makes clear that Mapping is responsible for populating incident field values, whereas Classification only chooses the incident type. Field configuration defines field metadata but does not map values. Layout configuration controls visual presentation only and does not populate fields.

Thus, option B (Mapping) is the function that converts event data into incident field values and is the correct answer according to the ingestion architecture documented in the XSOAR Admin Guide.
