Only 20-30 hours on our ISA-IEC-62443 learning guide are needed for the client to prepare for the test and it saves our client's time and energy. Most people may wish to use the shortest time to prepare for the test and then pass the test with our ISA-IEC-62443 study materials successfully because they have to spend their most time and energy on their jobs, learning, family lives and other important things. Our ISA-IEC-62443 Study Materials can satisfy their wishes and they only spare little time to prepare for exam.

## ISA/IEC 62443 Cybersecurity Fundamentals Specialist Sample Questions (Q125-Q130):

### NEW QUESTION # 125

Why is patch management more difficult for IACS than for business systems?

Available Choices (select all choices that are correct)

- A. Patching a live automation system can create safety risks.
- B. Many more approvals are required.
- C. Overtime pay is required for technicians.
- D. Business systems automatically update.

**Answer: A**

Explanation:

Patch management is the process of applying software updates to fix security vulnerabilities, improve functionality, or enhance

performance. Patch management is an essential part of cybersecurity, as unpatched systems can be exploited by malicious actors. However, patch management for industrial automation and control systems (IACS) is more challenging than for business systems, because patching a live automation system can create safety risks. According to the ISA/IEC 62443 standards, patching an IACS may have the following potential impacts:

- \* Patching may introduce new vulnerabilities or errors that compromise the availability, integrity, or confidentiality of the IACS.

- \* Patching may affect the functionality or performance of the IACS, causing unexpected or undesired behavior, such as process shutdowns, slowdowns, or failures.

- \* Patching may require downtime or reduced operation of the IACS, which may affect production, quality, or profitability.

- \* Patching may require additional resources, such as personnel, equipment, or testing facilities, which may not be readily available or affordable.

Therefore, patch management for IACS requires careful planning, testing, and validation before applying patches to the operational environment. The ISA/IEC 62443 standards provide guidance and best practices for patch management in the IACS environment, such as:

- \* Establishing a patch management program that defines roles, responsibilities, policies, and procedures

- \* for patching IACS components and systems.

- \* Identifying and prioritizing the IACS assets that need patching, based on their criticality, vulnerability, and risk level.

- \* Evaluating and verifying the patches for compatibility, functionality, and security before applying them to the IACS.

- \* Implementing and documenting the patching process, including backup, recovery, and rollback procedures, in case of patch failure or adverse effects.

- \* Monitoring and auditing the patching activities and outcomes, and reporting any issues or incidents.

#### NEW QUESTION # 126

How should CSMS organizational responsibilities or training be handled over time?

- A. They should remain constant.
- B. They should be expanded indefinitely.
- **C. They should be evaluated.**
- D. They should be ignored.

**Answer: C**

Explanation:

ISA/IEC 62443-2-1 emphasizes the importance of the ongoing evaluation of organizational responsibilities and training as part of continuous improvement within the CSMS. Periodic assessment ensures that personnel remain aware of their roles, are adequately trained, and that the program adapts to changes in the environment, technology, or threat landscape. The standard discourages keeping responsibilities static or expanding without control; instead, it advocates for regular reviews and updates.

#### NEW QUESTION # 127

The Risk Analysis category contains background information that is used where?

Available Choices (select all choices that are correct)

- A. Many other elements in the CSMS
- **B. Only the Risk ID element**
- C. (Elements external to the CSMS)
- D. Only the Assessment element

**Answer: B**

#### NEW QUESTION # 128

Which of the following is an element of monitoring and improving a CSMS?

Available Choices (select all choices that are correct)

- A. Increase in staff training and security awareness
- **B. Restricted access to the industrial control system to an as-needed basis**

- C. Significant changes in identified risk round in periodic reassessments
- **D. Review of system logs and other key data files**

**Answer: D**

### NEW QUESTION # 129

What should the identification analysis of discovered vulnerabilities determine?

- A. The cost of patch development
- **B. Root cause analysis**
- C. User interface improvements
- D. Marketing strategy for the product

**Answer: B**

Explanation:

ISA/IEC 62443 requires that vulnerability management go beyond detection and focus on understanding why vulnerabilities exist. Identification analysis is a critical step in this process.

Step 1: Purpose of identification analysis

The standard requires asset owners and suppliers to analyze discovered vulnerabilities to determine their origin and contributing factors. This ensures corrective actions address systemic issues, not just symptoms.

Step 2: Root cause focus

Root cause analysis identifies whether vulnerabilities result from configuration errors, insecure design, missing controls, or process failures. This aligns with the standard's emphasis on prevention and continuous improvement.

Step 3: Why other options are incorrect

User interface improvements and marketing strategies are unrelated to cybersecurity risk reduction. Cost considerations may follow remediation planning but are not the purpose of identification analysis.

Step 4: Lifecycle relevance

By identifying root causes, organizations can prevent recurrence and strengthen controls across the IACS lifecycle.

Thus, the correct answer is Root cause analysis.
