### WGU Introduction to IT Sample Questions (Q82-Q87):

#### NEW QUESTION # 82

What is a characteristic of hot storage?

- A. It offers relatively infrequent access.
- B. It allows for a slow restoration of operations.
- C. It uses lower-performance equipment.
- **D. It typically uses innovative equipment.**

**Answer: D**

Explanation:

Hot storage, often discussed alongside hot sites in disaster recovery, refers to storage and recovery capabilities that are ready for

rapid use with minimal delay. In IT disaster recovery terms, hot solutions emphasize high availability and quick restoration, which generally requires modern, high-performance, always-ready equipment and frequent data synchronization. Because hot storage is intended to support fast recovery time objectives, it is typically implemented using advanced storage systems, real-time replication, and automated failover technologies. The other options describe characteristics more aligned with colder approaches. Infrequent access and slow restoration are associated with cold storage or cold sites, where backups may be archived and recovery takes longer. Using lower-performance equipment also fits cold or warm recovery strategies, where cost savings are prioritized over immediate availability. Hot storage solutions are designed to minimize downtime and data loss, and this generally implies up-to-date, capable infrastructure rather than reduced performance. Therefore, among the options provided, the best characteristic of hot storage is that it typically uses innovative equipment.

### NEW QUESTION # 83

What does a router do?

- A. Extends the cable range and allows connections to be made by increasing the signal strength
- B. Provides services, such as website hosting and routing, for various devices
- C. **Manages traffic by maintaining a table of known devices on the network**
- D. Converts incoming analog data into digital and outgoing digital data into analog

**Answer: C**

Explanation:

A router manages network traffic by using a routing table to determine where data packets should be sent. In Information Technology networking, a router connects different networks, such as a home local network and the internet, and forwards packets based on destination IP addresses. The routing table contains information about known networks and the best path to reach them. This allows the router to direct traffic efficiently between networks and to serve as a gateway for devices on a local area network. Option A describes a server, which provides services like hosting websites or applications. Option C describes a repeater, which boosts or regenerates signals to extend cable distance. Option D describes a modem, which modulates and demodulates signals to convert between analog and digital forms for transmission over certain media. While modern home routers may also include switch and wireless access point features, the core routing function is traffic management using routing information. Therefore, the correct answer is the option describing maintaining a table and managing traffic, which is option B.

### NEW QUESTION # 84

What type of database uses parent-child relationships?

- A. Flat file
- B. **Hierarchical**
- C. Family file
- D. Embedded

**Answer: B**

Explanation:

Hierarchical databases use a parent-child relationship model. In this type of database, data is organized into a tree-like structure that implies a single-parent for each record. This model allows the representation of data in a hierarchy which is very much like a family tree. Each parent can have multiple children, but each child has only one parent (also known as a one-to-many relationship). The hierarchical database model was one of the first database models, historically used with mainframe computers. In this model, records contain information about their groups of parent/child relationships, similar to a family tree. If we consider a database of employees, each department would be a parent node, and each employee within that department would be a child node of the department.

References: The concept of parent-child relationships in databases is well-established and discussed in various educational resources and forums. For example, Stack Overflow provides explanations of how these relationships work in practice<sup>12</sup>. Additionally, other resources like phoenixnap.com explain how these relationships are established in databases<sup>3</sup>.

### NEW QUESTION # 85

Which image represents the basic structure of a computer network?

www.shutterstock.com - 48429052

Alt text: Desktop computer  
Long description: A desktop computer, keyboard, and mouse

www.shutterstock.com - 166095809

Alt text: Wireless router  
Long description: A wireless router with several Ethernet cables connected

Alt text: Server

Long description: A stand-alone server unit

Alt text: Cloud computing

Long description: A desktop computer, tablet, phone, and laptop connected to the cloud

- A. Exhibit D
- B. Exhibit C
- C. Exhibit B
- D. Exhibit A

**Answer: A**

**Explanation:**

the basic structure of a computer network is the one depicting cloud computing. In this image, a blue cloud labeled "Cloud" is connected to four different types of devices: a desktop computer, tablet, phone, and laptop.

Each device has an icon representing its type, and all devices are connected to the cloud, symbolizing data access and storage on the cloud.

#### **NEW QUESTION # 86**

Which operating system component schedules when each application runs?

- A. Driver
- B. Kernel

- C. User interface
- D. File manager

**Answer: B**

Explanation:

The kernel schedules when each application runs. In operating systems, scheduling is the process of deciding which program or process gets access to the CPU and for how long. This is essential for multitasking, where many applications appear to run at the same time. The kernel contains the process scheduler, which manages ready queues, assigns CPU time slices, handles context switching, and enforces priority rules so that system tasks and user applications run smoothly. In Information Technology, this function is part of core resource management, alongside memory management and device coordination. The user interface controls how the system is presented to users, such as command-line or graphical interfaces. The file manager focuses on storing, retrieving and organizing files and folders. Drivers translate operating system commands into device-specific actions for hardware such as keyboards, printers, and disk controllers. Since scheduling is a core OS responsibility handled internally, the correct component is the kernel.
