## API Source Inspector Electrical Equipment Sample Questions (Q70-Q75):

### NEW QUESTION # 70

Positive-pressurization and purging are based on the principle that an enclosure or room located in a classified location can:

- A. be supplied with clean air or inert gas at sufficient level.
- B. have concentrations of flammable gas or vapor.
- C. contain low levels of ignitable liquid gas.
- D. have arcing low voltage relays operating normally.

**Answer: A**

Explanation:

The correct answer is C. In hazardous or classified locations, positive pressurization and purging protect electrical equipment by preventing the surrounding flammable atmosphere from entering the enclosure. The operating principle is that the enclosure, cabinet, or room is supplied with clean air or an inert gas at a pressure and flow rate high enough to keep hazardous gas or vapor out before and during equipment operation. This allows equipment that might otherwise not be suitable for direct exposure to a classified atmosphere to operate safely when the purge and pressure conditions are maintained.

From an API source-inspection perspective, this aligns with the guide's emphasis on verifying compliance with the specified protection method, nameplate data, project drawings, and applicable hazardous-area requirements during inspection and surveillance. The inspector's concern is not simply whether the enclosure exists, but whether the correct protective concept has been applied and supported by proper fabrication, testing, and documentation. Options A and B describe the hazardous atmosphere itself, not the protection principle. Option D is incorrect because normal arcing devices still require a suitable protection method; pressurization does not rely on relays arcing normally.

### NEW QUESTION # 71

Apparent power is measured in:

- A. mhos.
- B. volt-amperes.
- C. vars.
- D. watts.

**Answer: B**

Explanation:

The correct answer is B because apparent power in an AC electrical system is measured in volt-amperes VA.

Apparent power represents the total electrical power supplied to a circuit and is the combination of real power and reactive power. Real power, which performs useful work such as turning a motor shaft or producing heat, is measured in watts. Reactive power, which supports magnetic and electric fields in inductive or capacitive equipment, is measured in vars. Apparent power is therefore the vector sum of these two and is expressed in VA or larger units such as kVA and MVA.

The other options are incorrect for this reason. Mhos is a unit of conductance, not power. Vars measure reactive power only. Watts measure true or active power only. In source inspection and quality surveillance of electrical equipment, understanding these distinctions is important when reviewing motor data sheets, transformer ratings, switchgear load data, and electrical test reports. Equipment such as transformers and generators are commonly rated in kVA or MVA because their thermal and current-carrying capability is tied to apparent power, making volt-amperes the correct answer.

### NEW QUESTION # 72

The insulation requirement referred to in NEMA ICS 1 defines clearance as the shortest distance:

- A. between the ground plane and the neutral conductor.
- B. over the surface of an insulating material between two conducting parts.
- C. a person can approach a live conductor without initiating a hazardous arcing incident.
- **D. measured through air between two conducting parts.**

**Answer: D**

Explanation:

The correct answer is C. In NEMA ICS 1, the term clearance refers to the shortest distance through air between two conductive parts. This is an important insulation concept used in industrial control and electrical equipment because adequate air spacing helps prevent dielectric breakdown, flashover, and unintended arcing when equipment operates at its rated voltage. During source inspection, this matters when verifying control panels, terminals, bus arrangements, relays, and other energized components where spacing must conform to design standards and applicable codes.

Option B describes a different concept known as creepage distance, which is the shortest path along the surface of an insulating material between conductive parts. Clearance and creepage are related but not the same, and inspectors must understand that distinction when reviewing equipment construction. Option A is not the NEMA definition of clearance, and option D refers more to personnel approach boundaries or electrical safety concepts, not insulation spacing requirements.

For API source inspection of control panels and similar assemblies, verifying proper air clearance is essential to confirming safe construction and compliance with specified electrical standards.

### NEW QUESTION # 73

Any reports, such as Material Test Reports, that have been modified or corrected should be:

- A. accepted after signatures are verified.
- B. rejected at the discretion of the source inspector.
- C. cause for immediate rejection.
- **D. accepted after clarification.**

**Answer: D**

Explanation:

The correct answer is A because, in source inspection practice, a corrected or revised report is not automatically invalid if the change is properly explained, traceable, and supported by the manufacturer's quality system. The source inspector's role is to review documentation for accuracy, traceability, consistency with specifications, and objective evidence of compliance. If a Material Test Report or similar record has been modified, the proper action is to obtain clarification, verify the reason for the correction, and confirm that the revised record remains authentic and controlled. Immediate rejection is too extreme unless there is evidence of falsification, loss of traceability, or unauthorized alteration.

This aligns with the API guide's emphasis on source inspection and quality surveillance activities rather than arbitrary dispositioning, and on verifying compliance through documented evidence and surveillance of the manufacturer's process. The guide is intended as a resource for the API Source Inspector Electrical Equipment body of knowledge, which includes document review, inspection planning, surveillance, and record verification as part of the overall source inspection process. Therefore, corrected reports should be accepted after clarification and verification, not rejected solely because they were revised.

### NEW QUESTION # 74

What does the second letter of the four-letter cooling code on liquid-immersed transformers identify?

- **A. Circulation mechanism for internal cooling medium**
- B. Internal cooling medium in contact with the windings
- C. External cooling medium
- D. Circulation mechanism for external cooling medium

**Answer: A**

Explanation:

The correct answer is B. For liquid-immersed transformers, the four-letter cooling code is used to describe both the cooling media and the method of circulation for the internal and external cooling systems. In this code structure, the first letter identifies the internal cooling

medium that is in contact with the windings, while the second letter identifies how that internal cooling medium circulates. This may be by natural circulation or by forced circulation, depending on the transformer design. The third letter then identifies the external cooling medium, and the fourth letter indicates the circulation method of that external medium.

This coding is important in source inspection because the cooling class affects transformer rating, heat dissipation capability, accessories, and verification of nameplate data. During inspection and surveillance, the source inspector checks that the specified cooling class on the nameplate, drawings, and test documentation matches the purchase requirements and transformer design. Misidentifying the cooling code can lead to misunderstanding of the transformer's thermal performance and service suitability. Therefore, the second letter specifically represents the circulation mechanism for the internal cooling medium.
